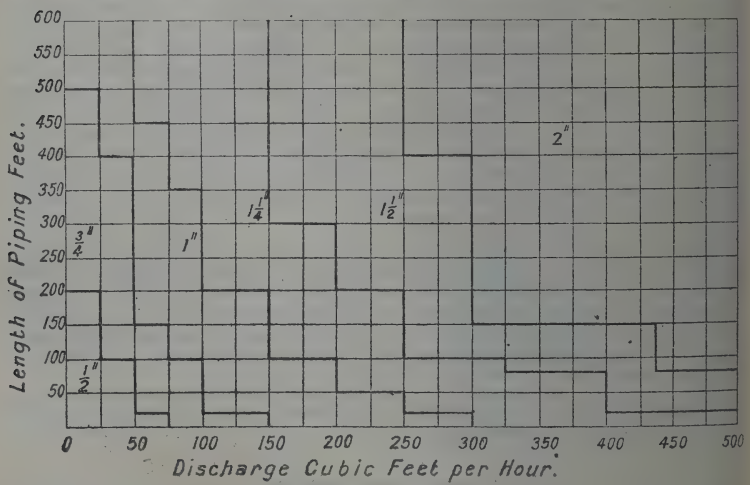
In the following diagram the point of intersection of consumption in cub. ft. per hour and length of pipe falls into an area indicating size of pipe for the work.



The diagram shows the size of pipe for the conveyance of a given quantity of gas. It is based on a fall of pressure between the extreme ends of the pipe of $\frac{5}{10}$-inch water gauge, and for

ordinary low-pressure gas supply it would not be desirable to have a drop greater than this. The diagram does not provide for piping smaller than $\frac{1}{2}$ in. because generally sizes smaller than this are only used for the branches to pendants or other apparatus consuming less than 25 cub. ft. per hour. Up to 10 cub. ft. per hour $\frac{1}{2}$ in. pipe is sufficient and for 10 to 25 cub. ft. $\frac{3}{4}$ in.

Flow of Gas in Mains.

Pole's Formula.

Let Q = the discharge of gas in cub. ft. per hour.
d = the diameter of pipe in inches.
p = pressure of gas in inches of water,
s = specific gravity of gas, air being 1
l = length of pipe in yards.

then,

$$Q = 1350d^2\sqrt{\frac{p\,d}{s\,l}};\quad d = \sqrt[5]{\frac{Q^2 s\,l}{(1350)^2 P}};\quad p = \frac{Q^2 s\,l}{(1350)^2 d^5};\quad l = \frac{(1350)^2 d^5 p}{Q^2 s}.$$

Unwin's Formula for High Pressure Gas Mains.

Let D = diameter of pipe in ft.
S = specific gravity of gas (air being 1).
L = Length of pipe in ft.
P_1 = initial pressure in lbs. per sq. inch absolute.
P_2 = final pressure in lbs. per sq. inch absolute.
C = coefficient of friction $= 0{\cdot}0044\left(1+\frac{1}{7D}\right)$.
U_1 = initial velocity of gas in feet per second.
U_2 = final velocity of gas in feet per second.
W = area of pipe in sq. ft.
Q = discharge in cub. ft. per hour,

then,

$$Q = 1{,}323{,}250\sqrt{\frac{P_1^2 - P_2^2}{P_1^2}\cdot\frac{P_1^2}{P_2^2}\cdot\frac{D^5}{CSL}};\quad U_1 = 468\sqrt{\frac{D}{CSL}\cdot\frac{P_1^2 - P_2^2}{P_1^2}};\quad U_2 = \frac{P_1}{P_2}U_1.$$

Table of Constants for Friction in Gas Mains.

(*Professor Unwin.*)

Everite Gas Piping.

(*Bell's Poilite and Everite Co., Ltd., Southwark St., London, and Peter St., Manchester.*)

Everite piping is specially manufactured for the gas industry, and all the usual accessories can be obtained, including flue pipes, bends, bafflers, cone caps, etc., etc.

Gas Pressures.

Generally, gas pressures (in a factory, for example) are sufficiently constant for the correct working of gas-consuming apparatus, but occasionally owing to piping being of insufficient size a variation in the consumption will cause a variation of pressure. The best remedy is to relay or supplement the piping in the building, but, as a temporary measure, governors can be installed on any apparatus which needs a fairly constant supply of gas. The Stott, Peebles, Tilley, Sugg, and Williams governors are typical of this appliance. They maintain a constant pressure on their outlet regardless of wide variation at the inlet.

Gas Meters.

Size of Meter.	Normal Capacity.	Safe Maximum Capacity.
Lights.	Cub. ft. per hour.	Cub. ft. per hour.
5	30	60
10	60	100
20	120	200
30	180	300
50	300	450
60	360	480
80	480	600
100	600	750
150	900	1,100
200	1,200	1,500
250	1,500	1,900
300	1,800	2,300
400	2,400	3,000
500	3,000	3,700
600	3,600	4,500
800	4,400	6,000
1,000	5,000	7,500

It is desirable that the normal capacity should not be exceeded for continuous working, as there will be some risk of the meter breaking down and the supply of gas temporarily stopped. If additional gas-consuming apparatus is installed a larger meter should, if necessary, be used.

Gas Tests.

Gas Tests as Prescribed by the Metropolitan Gas Referees.

As gas is now sold on the 'Therm' basis, the determination of calorific power is the most important of the official tests. Illuminating power, however, is frequently required as a matter of interest rather than importance, and for this reason the test is given below.

(1) *Illuminating Power.*

Although calorific power is taking the place of illuminating power as a standard of quality, the latter test is still carried out in many instances.

This test is made by a photometric comparison between (*a*) a standard Argand burner called the Metropolitan Argand Burner No. 2, of which a part section drawing is given in fig. 1;

(*b*) a standard flat-flame wing burner $\left(\text{Bray's } \frac{G}{L} \text{ 5 ft. } \frac{15}{10}\right)$ having a slit 0·028 in. wide, and a 10-candle power standard lamp burning a mixture of pentane and air. The standard lamp is shown in fig. 2. A is a receptacle subdivided by seven alternate partitions which do not extend the full width of the chamber; so that air, drawn in through the cock S^1, by means of which the supply is regulated, is caused to traverse the surface of the liquid, with which the chamber is filled to about two-thirds of its height, eight times. The mixture of gas and air passes through the cock S^2 to a burner B, consisting of a steatite ring pierced with thirty holes between 1·5 and 1·25 mm. in diameter. The flame is viewed through a mica window in G. Careful adjustments are made to regulate the height of the flame and the concentricity of the chimney D.

The pentane for the lamp is prepared and tested in the following manner:—Light American petroleum, such as is used for making air-gas, is rectified by three successive distillations, at 15° C., 50°, and 45°. The distillate is shaken up from time to time, during two periods of not less than three hours each, with one-tenth its bulk of (1) strong sulphuric acid, (2) solution of caustic soda. After this it is again distilled, and that portion which comes over between the temperatures of 25° and 40° is collected. This consists chiefly of pentane, with small quantities of other homologues the presence of which does not affect the light of the lamp.

The density of the liquid pentane at 15° C. should lie between 0·6235 and 0·626 compared with water of maximum density.

Any admixture with pentane of hydrocarbons having a higher photogenic value, such as benzene or amylene, must be avoided. The presence of these may be detected by the following test:—Pour into a stoppered 4-oz. bottle of white glass 10 c.c. of dilute nitric acid, specific gravity 1·32; add 1 c.c. of a dilute solution of potassium permanganate (1 gr. in 200 c.c.). Pour into the bottle 50 c.c. of the sample of pentane, and shake strongly during five successive periods of 20 seconds. If there is an admixture of as much as ½ per cent. of amylene or benzene, the pink colour will disappear.

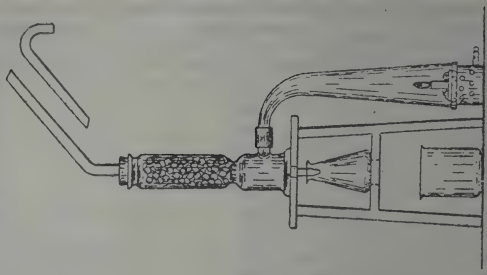

FIG. 3.

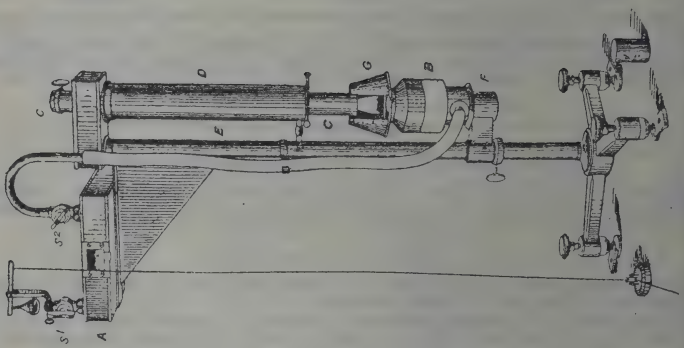

FIG. 2.

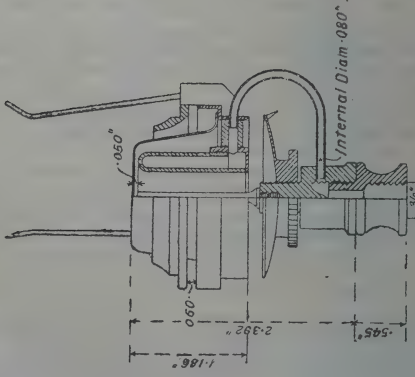

FIG. 1.

The photometric comparison is made by producing equality in the illumination of a white paper screen by shifting the test burner nearer to or further from the screen; the result, after applying barometric and temperature corrections, is expressed to the nearest hundredth of a candle.

(2) *Test for Sulphuretted Hydrogen.*

The gas is passed through a glass vessel in which are suspended strips of bibulous paper moistened with a solution of 6·5 grams acetate of lead crystals in 100 c.c. water. The gas having been turned into the vessel long enough to sweep out the air, is ignited at the issuing orifice, and when it has burned for three minutes one of the slips is compared with a slip similarly moistened but not exposed to the gas. The gas is taken as exhibiting a trace of H_2S if the exposed is unmistakably darker than the unexposed slip.

(3) *Tests for other Sulphur Compounds.*

Ten cubic feet of gas is burned in a Bunsen burner at the rate of ·5 cubic foot of gas per hour. The stem of the burner is surrounded with about 2 ounces of sesquicarbonate of ammonia, and the combined products of combustion and volatilisation are collected by means of a trumpet

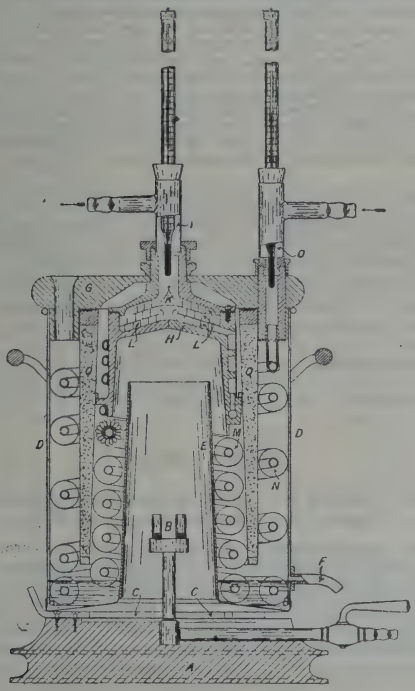

FIG. 4.

glass fitted over the burner and salt, an air-way being provided for the burner in the stand upon which it is placed (see fig. 3). The products are condensed as far as possible in the upper glass vessel, which, to aid the condensation, is filled with a number of glass balls about .5 mm. in diameter. The distillate, collected in a beaker placed beneath the bottom orifice of the condenser as shown, is poured, together with the washings of the trumpet and condenser, into a measure glass. A sample $\left(\frac{1}{n}\text{th part}\right)$ of the liquid is treated with hydrochloric acid in a covered beaker until there is an excess of acid, and then raised to boiling point; an excess of a barium

chloride solution is added, and the boiling continued for five minutes. After standing for a time barium sulphate settles; the latter is filtered off and washed with hot distilled water, in order to remove all traces of ammonium and barium chlorides. (A sample of the washings is tested for this in a test tube with silver nitrate, the washing being continued until no cloudiness is produced by the nitrate.) The filter paper with the barium sulphate is heated in a weighed platinum crucible until the paper is removed. When cool the crucible is placed in a desiccator over strong sulphuric acid and again weighed. The number of grains of barium sulphate thus obtained, multiplied by $\frac{11n}{8}$ (n being the quantity of liquid under test as above), gives the grains of sulphur per 100 cub. ft. of gas. This figure is corrected for barometric and temperature variations as in the case of the illuminating power test.

(4) *Tests for Calorific Power.*

These are carried out by observations taken by means of the special calorimeter illustrated in fig. 4, in which water flowing at a calibrated rate is heated by a double burner consuming the gas at a rate of $\frac{1}{12}$ cub. ft. per minute. The calorimeter having been set up, the burner lighted, and the water flow adjusted, the heating is allowed to proceed for not less than half an hour. Four readings of the inlet thermometer and fifteen readings of the outlet thermometer are taken at periodic intervals, during which the discharged water is collected in a measuring vessel and the operation timed by means of a chronograph. The temperature of the air about the apparatus, the gas in the meter, and the effluent gas are also observed. The mean of the four readings of the inlet temperature is subtracted from the mean of the fifteen readings of the outlet temperature, and the difference is multiplied by 3 and by the number of litres of water collected. The product is divided by a tabular number.* The difference in degrees Centigrade of the temperature of the effluent gas and of the surrounding air divided by 6 is added to the result previously found if the effluent gas is the warmer of the two, or subtracted if the effluent gas is the cooler. The result is the gross calorific power of the gas in calories per cubic foot (c).

In addition to the foregoing, the amount of condensed water resulting from the combustion of the gas is measured. For this purpose the condensation water is led into a flask not less than 20 minutes after the calorimeter has been set up. The amount collected in not less than 30 minutes is measured, the time of collection being accurately noted on the chronograph. The number of cubic centimetres collected is multiplied by the number of seconds and by the number 1·86 (a). The number of seconds during which the condensed water is collected is multiplied by the tabular number (b). The first product (a) divided by the second (b) and subtracted from the gross calorific power (c) gives the net calorific power in calories per cubic foot. The gross and net calorific power in British thermal units is obtained by multiplying the corresponding numbers of calories by 3·968.

The meters used for these tests are of the 'wet' type, having a calibrated capacity of $\frac{1}{12}$ cubic foot per revolution of the drum. The drum carries an index-hand moving over a dial divided into 100 divisions, and the meters are provided with a thermometer for measuring the normal gas temperature.

ACETYLENE.

(Contributed by the late Professor Vivian B. Lewes, F.C.S., F.I.C.) Revised by Charles Bingham, C.E.

Acetylene, which is a gaseous compound of hydrogen and carbon, represented by the formula C_2H_2, is a colourless gas with a density of 0·92. As ordinarily prepared, it has a strong and very penetrating odour, but when purified from minute traces of other gases, invariably present with it in its crude state, has a not unpleasant ethereal odour. It can be converted into a liquid at a pressure of 21·53 atmospheres, at a temperature of 0° C., and liquefies under ordinary atmospheric pressure when cooled to a temperature of −82° C. The critical point of the gas is 37° C., and at this temperature the pressure has to be raised to 68 atmospheres for its liquefaction.

Acetylene is readily soluble in water, which at normal temperature and pressure takes up about its own volume of the gas; its solubility in other liquids is given in the following table:

100 Volumes of		Volumes of Acetylene.	100 Volumes of		Volumes of Acetylene.
Brine	absorb	5	Fusel oil	absorb	100
Water	,,	110	Benzene	,,	400
Alcohol	,,	600	Chloroform	,,	400
Paraffin	,,	150	Acetic acid	,,	600
Carbon disulphide	,,	100	Acetone	,,	2,500

* The tabular number depends upon the barometer reading and the normal temperature of the gas passing through the meter.

Extended researches by Bistrow and Liebreich upon the toxic properties of acetylene show that it acts upon the blood in much the same way as carbon monoxide, but exhaustive experiments show that it is less poisonous than ordinary coal gas.

Acetylene forms compounds of an explosive character with copper and silver, and at first this was thought to be a great drawback to its general use; but experience has shown that these fears were unfounded, and that brass gas fittings, when gas-tight, can be used with perfect safety.

Acetylene, when heated, polymerises, like most hydrocarbons, i.e. it is partly or wholly split up, and the resulting gas is usually a mixture of acetylene itself and poorer gases, such as hydrogen, methane, etc., while tarry compounds and even solid carbon are formed, if the heating is carried far enough.

This is a matter of the utmost importance to acetylene users. For lighting purposes, it means that a poor light is given; for oxy-acetylene welders it means that the temperature at the blowpipe is reduced considerably, indeed in some cases it has proved impossible to make satisfactory welds, owing to the poor quality of the gas.

These troubles arise almost exclusively with water-to-carbide generators, which are often faultily designed, so that overheating is bound to occur.

Experiments lately carried out by the French Acetylene Office have shown that polymerisation starts in an ordinary commercial generator at about 130° C., *i.e.* at a much lower temperature than was originally believed to be the case. Unfortunately many generators sold in this country act by driving the water away from the carbide container, when a certain amount of gas has been generated, leaving the live carbide surrounded by a mass of moist lime sludge, which is again surrounded by a blanket of acetylene. Acetylene, however, is a far poorer conductor of heat than water. At the instance of the writer, the heat conductivity of acetylene was ascertained by the National Physical Laboratory, we believe for the first time. It was found to be 0·000043 c.g.s., or only about one thirty-second of that of water. If, therefore, decomposing carbide is surrounded by acetylene instead of by water, only about 3 per cent. of the heat is carried off in a given time, which could be carried off by water, and the writer has seen sludge become actually visibly red under such conditions.

It is therefore of the utmost importance that acetylene users should be careful to see that they select acetylene generators in which there is always an ample supply of water in constant contact with the carbide, or constantly surrounding the carbide containers. It may also be pointed out that the better the carbide is, the more quickly it is attacked by water and, in consequence, the greater the quantity of heat liberated in a given time by its decomposition.

A new type of acetylene generator which differs radically in its generating chamber from anything previously used, although of extremely simple construction, has been put on the market in this country. The system has been in considerable use for about two years, and has given complete satisfaction.

In contact with air acetylene inflames at a temperature of 480° C. and burns with a flame which, when properly spread out so as to obtain a large quantity of oxygen, emits more light than any other gaseous compound of carbon and hydrogen.

Gas.	Candle hours per 5 cub. ft.	Carcel hours per cub. metre.	Gas.	Candle hours per 5 cub. ft.	Carcel hours per cub. metre.
Methane	5·2	3·5	Propane	56·2	40·0
Paris gas	13·2	9·6	Ethylene	70·0	49·0
London gas	16	11·5	Butylene	123·0	86·0
Ethane	35·7	25·0	Acetylene	240·0	168·0

Professor Clowes has shown that acetylene has a wider range of explosibility when mixed with air than any other combustible gas, the limits in percentages being as follows:

	Per cent.		Per cent.		Per cent.
Acetylene	3 to 82	Carbon monoxide	13 to 75	Methane	5 to 13
Hydrogen	5 to 72	Ethylene	4 to 22		

Acetylene is made commercially by acting upon a compound known as calcium carbide (CaC_2) with water, when acetylene gas is liberated and calcium hydrate (slaked lime, $Ca(HO)_2$) is formed.

Calcium carbide is made by fusing together very pure coke (or high-carbon anthracite coal) and very pure lime by the intense heat of the electric furnace. No other way of heating the mixture to the required temperature has yet been discovered, although many attempts have been made; for instance, by the use of the oxy-acetylene blowpipe.

Acetylene generators, in which the interaction of the calcium carbide and water to generate the gas takes place, may be either automatic or non-automatic. In the former class, devices are used to stop the generation of the gas automatically, by cutting off the supply of water or the supply of carbide, thus doing away with the need of a large store-holder for the gas, whilst in the non-automatic class the action is allowed to continue until all the carbide is decomposed, the gas being stored in a holder from which it is used as required.

In making acetylene, water may be brought in contact with the carbide either by adding it to the carbide, or by adding the carbide to water.

The overwhelming majority of acetylene generators in practically all countries are now constructed on the water-to-carbide system.

Of late years the automatic type of apparatus for the generation of acetylene has almost entirely superseded the non-automatic type, owing to the very large quantity of acetylene now being required for the oxy-acetylene welding process.

Experience has shown that automatic generators can be constructed with a high factor of efficiency, while the capital outlay per unit of gas generated is considerably less than in the case of non-automatic apparatus.

Owing also to the much smaller space occupied by the automatic type, it has also been found much more convenient for private use.

Until comparatively recent times, the pressure customary in acetylene generators was from 4 to 8 inches water-column, these limits having been found to give the most satisfactory results for lighting purposes. The advent of the oxy-acetylene welding blowpipe, however, soon caused experiments to be made with higher pressures, with the most favourable results. To-day the general tendency in most countries is to have the acetylene under slightly higher pressure than the oxygen in the welding blowpipe, it being claimed that less oxidation of the metal took place under these conditions and that there was less chance of the right proportion of the two gases being interfered with by accidental obstruction in the blowpipe, and, lastly, there was less tendency for the flame to flash back.

In consequence of this movement, the Governments of the United States, Canada, Switzerland, and Denmark now allow a maximum pressure of 1 atm. in acetylene generators for welding, and Germany is on the point of adopting this maximum pressure also. Very interesting details of tests have been published by the Government Bureau of Standards in the United States.

The oxy-acetylene blowpipe has been most successfully used for a considerable time for case-hardening various parts of machinery, and in particular the gear-wheels and other parts of motor cars. Lately a most important development has taken place in this direction, the blowpipe having come into the most extensive use, not only for cutting and repairing rails, but for applying an exceedingly hard surface, to a depth reaching even the high figure of ¼ inch and more to the entire rail system of electric tramways.

The improvement shown in the wearing properties of rails is shown by the following figures:

	Wear of rails in 12 months.		No. of cars
	Untreated.	Treated.	carried.
Bristol	0·045	0·0157	300,000
Liverpool	0·030	0·0125	200,000

The rails are hardened *in situ*, without otherwise interfering with the track in any way.

When acetylene first made its appearance, its use was confined almost entirely to lighting detached buildings, motor-cars, and cycles.

The advent of electric sets materially reduced the field for acetylene for lighting purposes, but recently there has been a decided revival in this direction, owing to the enormously increased construction of houses of the bungalow type, large numbers of which are situated so far from a centre of supply of coal-gas or electric current that the cost of laying the necessary supply pipes or cables makes the capital outlay too great, in view of the modest requirements per bungalow.

In such cases the very low capital outlay required for an acetylene outfit, its extreme simplicity, and the beautiful light it gives, have made this form of lighting extremely popular.

The use of the oxy-acetylene blowpipe has continued to increase during the past year; indeed these and other applications have so greatly extended the use of acetylene that whereas the consumption of carbide before the war amounted to about 28,000 tons, it rose in 1925 to 40,000 tons per annum. There was a set-back, owing to the difficulties in the coal industry, but at the time of writing a consumption of approximately 40,000 tons a year has again been reached.

The use of acetylene in other directions than as a combustible again made great strides in the past year. One of the most interesting new derivatives is the 'Meta' block, which has been placed on the market by a Swiss firm. This block resembles in appearance solidified methylated spirit, but in its properties it is greatly superior, inasmuch as the block does not liquefy when burning, nor evaporate even if exposed to the air for many months.

Acetylene as obtained from ordinary generators contains a certain amount of impurities. The use of the acetylene blowpipe for welding high-class steels has shown more and more clearly the necessity for removing these impurities from the gas, a purification which can easily be effected by the use of such purifying materials as catalysol, heratol, etc.

One pound of commercial calcium carbide, when acted upon by water, yields on an average about 4·5 cub. ft. of the gas.

Before the war the price of carbide was about £12 10*s.* per ton, packages included. The price is now about £16 to £18 in the United Kingdom, while it is still higher in many of the countries producing it.

Dissolved Acetylene.

By an Order in Council issued in 1897 the compression of free acetylene was made illegal, but further orders were issued in 1901 and 1912 exempting the process now known as 'dissolved acetylene.' This is acetylene thoroughly purified and washed, and compressed into steel cylinders previously filled with a porous mass and having a fixed quantity of acetone added. Acetone is a liquid hydrocarbon, having the property of absorbing 25 times its own volume of acetylene at one atmosphere and 15° C.

For each additional atmosphere of pressure, the same proportion of gas is absorbed, but an lowance has, of course, to be made not only for the volume occupied by the porous filling of ıe cylinder, but, in addition, in order to allow for expansion, so that it is customary to charge ıese cylinders with only 43 per cent. of acetone.

A cylinder will therefore in actual practice contain about 100 times its own volume at 10 mospheres pressure and about 150 times at 15 atmospheres pressure.

In order to show the enormous capacity for storing light obtained in this manner, it may mentioned that the standard oil-gas cylinder in use on railways has a capacity of 14 cub. ft. atmospheric pressure. As the oil-gas is usually compressed to 12 atmospheres, this gives gas volume of 168 cub. ft., which, if filled with oil-gas, will supply eight burners using 2 ft. r hour and burning eight hours per day, for about a day and a half. If this cylinder were led with porous material and acetone in the manner described above, and charged with acetylene 15 atmospheres, its capacity would be 2,100 cub. ft., or sufficient to supply eight acetylene rners of 1 cub. ft. each (giving a most brilliant light), for about thirty-three days (basing on ght hours' lighting per day), before the cylinders would require to be re-charged.

The possibility of obtaining acetylene in compressed form opens up a very wide field for the pansion of its utility.

The tests carried out by the Home Office Authorities before issuing the exemption order of 01 were exhaustive, and furnished satisfactory proof of the safety attending the process of nufacture and the use of the cylinders.

Storage of Dissolved Acetylene.

Acetylene dissolved in acetone and stored, under a pressure not exceeding 225 lbs. per sq. in. a vessel filled as completely as possible with some porous substance is not deemed an ex- sive, and can therefore be manufactured, stored, and used without risk of infringing the plosives Act.

(See also 1919 Order in Council, 'Dissolved Acetylene.')

Porous Material.—Various types of filling are in use and appear to give satisfaction. In s country the Kapok filling, patented by *Allen-Liversidge, Ltd.*, is chiefly in use. The porosity the material should not exceed 80 per cent. The material should completely fill the receptacle, l should contain no pockets or cavities.

The Solvent.—Acetone is the most suitable commercial solvent, but substitutes for acetone ıld be permitted. The solvent should not completely fill the porosity of the material under r rise of temperature likely to be met with in practice.

Pressure Allowed.—The pressure can be 225 lbs., provided the cylinders used are of the solid wn type, the pressure to be measured at 60° F.

The Cylinders.—The cylinders should be made of mild steel containing not more than 0·25 cent. of carbon and not more than 0·05 per cent. each of phosphorus and sulphur. The test ssure should be four times the working pressure, and should be maintained for not less than een minutes. All cylinders should be annealed, but the use of fusible plugs, at present npulsory on acetylene cylinders, should be discontinued, as they are apt to become loose and, ther, in the event of fire occurring, may actually lead to the fire being augmented.

It is not considered necessary to impose any conditions as regards the retesting of acetylene inders beyond requiring them to be thoroughly examined visually at intervals. The form of sting to which oxygen and other cylinders are subjected cannot readily be applied to tylene cylinders with their content of porous material and solvent.

Acetylene Lighting.

For the illumination of buildings, towns, and large areas by acetylene, generators of some able type are in general use.

Dissolved acetylene is used successfully from an economical and efficient point of view for ıy purposes where a constant supply of acetylene is required, and is particularly adaptable re space available for the apparatus is strictly limited.

In the matter of motor vehicle lighting it has been very extensively adopted. A cylinder taining acetylene absorbed in acetone under pressure and of convenient size is attached to footboard or other suitable position on the car. Such a cylinder contains a sufficient supply ıcetylene to meet the requirements for the lighting of the necessary lamps. The time for ch the supply is available is variable according to the rate of consumption; the pressure of in the cylinder is reduced by an automatic governor or regulating valve, and the supply in service pipes is maintained at a constant pressure to the lamps.

The standard automobile cylinders contain 20 cub. ft. and 40 cub. ft. of dissolved ylene, and by the exchange system originated by the manufacturers it is possible for s to obtain refills at practically all important garages throughout the country.

Larger vehicles, such as motor omnibuses, mail vans, motor lorries, etc., may be equipped outfits of larger capacity to meet the requirements of any particular case.

Another recent departure is the manufacture and circulation of cylinders containing dissolv acetylene of such capacity to meet the demands of motor cyclists. These cylinders a standardised and contain 5 and 10 cub. ft. of acetylene and, as with the standard cylind for automobile work, they may be exchanged throughout the country.

For buoy and coast lighting dissolved acetylene has many advantages. The purity of t gas in this form, which is assured before compressing, gives the light increased brilliance a greater penetrating power, hence a shorter light period can be employed than with any oti illuminant. Various special apparatus are in use, in which flashes of long or short duration obtained by automatic means, the light being extinguished between the flashes instead of obscu (a small bypass burner remaining alight), thus economising gas. In some cases a flash of short duration as one-tenth of a second is obtained, with perfect accuracy and flame. By mea of this economical consumption and the great storage capacity of a comparatively small cylind a gas supply for periods as long as 12 months can be easily carried on a buoy, no attention bei required until the gas is exhausted, when the cylinder is disconnected and replaced by a full o The cylinders may be arranged in the form of a battery where larger consumption is involved.

Owing to the smallness of space required for acetylene in this form it is particularly adapta for lighting railway coaches, yachts, and small craft. The effect of atmospheric temperat on the gas in this form is almost negligible, and other advantages are obtained by reason of purity of gas and the elimination of handling carbide, water, waste and residue, and by the f that the gas in this form can be stored indefinitely without deterioration.

The applications of this form of acetylene are ever increasing, and it has been recently appl with success to cinematographs, searchlight, signalling and projection work, where a small a compact plant consistent with efficiency is required.

The most recent application for illuminating purposes is that of its adoption for portable ha lamps for mining and other similar purposes.

Lately acetylene buoys have commenced to displace other forms of coast-lighting to a v considerable extent. Such buoys take a very large charge of calcium carbide, usually one two tons. They are entirely automatic, require practically no attention, and as they run for to twelve months before requiring recharging, they form an exceedingly economical means f coast and harbour-lighting. Another great advantage is the fact that the light can recognised at a much greater distance than that of the oil, or oil-gas, buoys previously used.

PETROL AIR GAS.

(Contributed by E. Scott-Snell, A.M.S.E.)

Petrol gas is made by impregnating air with the vapour of petroleum spirit, this mixture be sent through pipes in the usual way for combustion with incandescent mantles. The essen features of an apparatus for producing this gas are an air compressor, a carburettor—in wh the air and petrol are brought into contact—and a gas-holder from which the pipe service is In automatic apparatus, *i.e.* machines in which gas is made according to the demand, the hol is also used as a governor for controlling the supply of air and petrol to the carburettor. relative proportions of air to petrol are very important: in fact, upon the relation of these in dients, and the constancy of this relation under varying load and climatic conditions, the suc or failure of any apparatus must depend. As a mantle is used for light-giving, a flame is requi at the burner which shall give the highest possible temperature, *i.e.* the amount of air mi with the petrol vapour must be such as to completely combust it. With the more volatile sp mainly hexane (C_6H_{14}), used for making this gas, complete combustion is assured when appr mately two volumes of vapour are mixed with 98 volumes of air. This is calculated from typical equation $2C_6H_{14}+19O_2=12CO_2+14H_2O$ representing the combustion of the chief c stituent of light spirit. At present, opinion seems to be divided as to the advisability of send such a mixture—which from its composition is obviously an explosive one in a confined sp such as a gas-holder—through the system. It is found, however, that when the percentag vapour in the mixture exceeds 4½ per cent., e.g., a 5 per cent. or 6 per cent. mixture, the ga incombustible without the addition of further air, and in the better class machines advantag taken of this fact to make a slightly richer gas than 4½ per cent., diluting it with the extra required for complete combustion by the aid of Bunsen burners.

The air-compressing apparatus of a petrol gas machine may be actuated by any motive po but as the work of forcing the gas through the pipes is comparatively light, nothing more powe than a hot-air motor or wound-up weights is usually required. In a good apparatus, the rela amounts of air and petrol are mechanically measured before passing to the carburettor, so t constancy of mixture is obtained under all conditions of temperature within wide limits. W other means are adopted, such as leading the air across a bath of petrol, selective evapora takes place, producing erratic results, the make of gas varying with every change of temperat In fact, attempts to make apparatus of this sort automatic almost inevitably end in failure.

Petrol gas is probably one of the safest lighting mediums known, by reason of the small compass over which mixtures of petrol vapour and air are explosive (1½ per cent. to 4½ per cent.. c.f. acetylene 3·3 per cent. to 52·3 per cent., coal-gas 7·9 per cent. to 19·1 per cent.) and the fact that over 90 per cent. of the escaping gas from any leak is air. It is also non-asphyxiating.

The gas varies in calorific value according to the proportions of the mixture and the spirit used, but a 6 per cent. mixture from 0·680 sp. gr. petrol has a gross calorific value of nearly 300 B.T.U. per cubic foot. Although this is a comparatively low figure, cooking and heating can be efficiently performed with suitably proportioned burners.

One gallon of light spirit gives 5,000 candle-power hours (Lewes). With petrol at 1*s.* a gallon this is equivalent to 2·4*d.* per 1,000 candle-power hours. The Government tax of 3*d.* per gallon is remitted when petrol is used for purposes other than propelling road vehicles.

Petrol gas can be stored almost indefinitely over water, but since a small 'Bijou' mantle requires anything from 4 to 12 cub. ft. per hour (according to whether a 6 per cent. or 2 per cent. mixture is used) the storage of any reasonable quantity of the gas entails the use of very large holders. Hence the advantage of the weight-driven type of automatic generator.

Attempts are being made to effect economy by using the less volatile petrols of 0·720 to 0·760 sp. gr. for lighting purposes, such as are in general use for motor cars. The physical characteristics of these spirits, however, are such that they do not lend themselves readily to cold carburation, for either considerable quantities will pass through the carburettor unvapourised, or if heat is used to evaporate them, heavy condensation is unavoidable in the pipe service, which must necessarily be very carefully laid to provide for it.

An explosive (or 'weak') mixture in the pipes and holder is unavoidable if heavy spirits are used, since they are not sufficiently volatile to allow of the use of a 'rich' mixture. See also Wescott-Snell on 'Petrol Air Gas,' Soc. of Eng. Journal and Trans., March 1911; Illuminating Engineer's Soc. Journal and Trans., February 1913.

Heating Value and Candle-Power of Petrol-Air Gas.

According to *The Snercold Engineering Co.*, as the result of tests of a variety of different brands and grades of petrol, the fair average heating value of a gallon of petrol is 143,500 B.Th.U., and the maximum candle-power hours that can be obtained under the best conditions is 6,025. The following table shows different mixtures in percentages of petrol vapour used; for calculation purposes the heating value has been taken as 143,000 B.Th.U., and the candle-power hours as 6,000 per gallon.

TABLE SHOWING VARIOUS MIXTURES OF PETROL-AIR GAS.

Mixture Percentage of Petrol Vapour.	Gallons per 1,000 Cubic Feet of Gas.	Heating Value B.Th.U. per Cubic Foot.	Cubic Feet of Gas to the Gallon.	Candle-power Hours per Cubic Foot.
6	2·184	312	458·3	13·104
5½	2·0	286	500	12·0
5	1·82	260	555	10·92
4½	1·638	234	612	9·828
4	1·4638	208	687·5	8·7828
3½	1·274	182	785·7	7·644
3	1·092	156	916·6	6·552
2½	0·91	130	1100	5·46
2	0·728	104	1375	4·368
1½	0·546	78	1833·2	3·276

The heating value of coal-gas varies from 420 to 550 B.Th.U. per cubic foot according to the source of supply.

THE SNERCOLD PETROL-AIR GAS PLANT.

In this plant a 5½ per cent. mixture is generated. The carburettor will vaporise petrol in very cold weather without the application of warmth; in it, the temperature of evaporation falls below as 49° of frost (−17° F.), which is well below the lowest winter temperature in this country; for this reason condensation is impossible with the apparatus. The arrangement extracts the moisture from the air, which is carefully kept from contact with water, and thus the air on carburation is dry; hence it always absorbs the correct proportion of petrol, and a uniform gas is produced without possibility of variation. The air cannot obtain more than the predetermined quantity of petrol, while from the design of the carburettor it must take all that is supplied. When no gas is being consumed the apparatus is entirely inactive.

THE WELLS LIGHT.

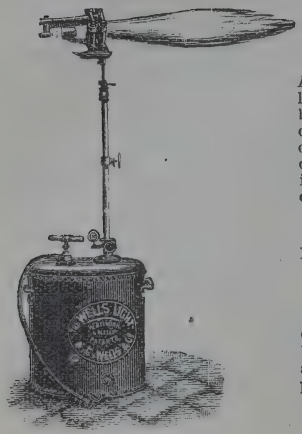

FIG. 5.

Wells Light (*A. C. Wells & Co., Midland Road, St. Pancras, London, and Manchester*), fig. 5, is a portabl light, up to 3,000 candle-power, produced from oil spra blown horizontally ; the flame is quite unaffected by win or rain. The arrangement is self-contained, and th containing vessel can easily be charged with oil and a during working, while accessibility of all parts for clean ing, combined with strength and simplicity, are feature of the lamp.

The most useful sizes are as follows :

		Ins.	In
No. 0, 500	candle-power ; size of tank	13½ × 9	
„ 1, 500 and 1,500	„ „ „ „	16 × 1	
„ 3, 2,500	„ „ „ „	24 × 1	

The Wells Light has been adopted by more than Governments, for military and naval purposes, and al by the principal Railway Companies in England ar abroad. The Wells Light principle is also applied powerful Heating Plants, Road Drying Appliances, Brazi Outfits, &c.

(For ' LIGHTING,' see Section XXXVIII., Part III., p. 2521.

HEAT TREATMENT OF GAS CYLINDERS.

(*Second Report.**)

In view of experiments made by the Gas Cylinders Research Committee the Committee agr that the periodical re-heat treatment of carbon steel gas cylinders which have not been obvious damaged, serves no useful purpose, and they recommend that the practice be discontinued.

* ' Periodical Heat Treatment.' Published for the Department of Scientific and Industri Research by H.M. Stationery Office. Price 2s. 6d. net.

HEATING.

(Revised by J. Roger Preston, Member of the Council of the Institution of Heating and Ventilating Engineers.)

General.

The unit of heat or British Thermal Unit (B.Th.U.) is the heat required to raise the temperature of 1 lb. of water 1° F.; the unit of surface is the square foot; the unit of pressure is the pound per square inch; the unit of temperature is the degree Fah. Air may be expressed in cubic feet or in pounds weight, and Table A shows how these are convertible.

TABLE A.

Air Temperatures.	12°	22°	32°	42°	52°	62°	72°
Relative Volume of dry air at given temperatures (Volume at 32° F. = 1) . . .	·960	·980	1·00	1·02	1·04	1·06	1·08
Weight per cubic foot in pounds	·0842	·0824	·0807	·0791	·0776	·0761	·0747

NOTE.—The volume of 1 lb. of dry air at 32° F. = 12·38 cub. ft. For any other of the above temperatures, multiply by the relative volume.

OPEN FIRE GRATES.

It would seem that the open fireplace is not the criminally wasteful contrivance that it is commonly supposed to be, and that the 'well' type of fireplace is open to criticism. 'The pleasant British practice of sitting round the open fire,' says the Fuel Research Board Report, 1918–19, 'is amply justified from the scientific point of view, when we know that so much as one-fifth of the total heat of the coal is immediately available for absorption by the sitters if they constitute themselves into a sufficiently close screen around the fire.' In addition to the directly measured radiant heat, the open fire, it seems, is to be credited with heat conducted, radiated, and convected from the fireplace, chimney, and walls to an extent which is such that all together some 60 to 70 per cent. of the heat of the coal is utilised in warming the room and the general fabric of the building.

The following hints as to the best method of altering ordinary house fire-grates, so that they will be more effective and economical, have been circulated by the Royal Institute of British Architects: 'Line your grates with fire-bricks. See that the fire-bricks are high enough to stand up above the fire. Take care that the back brick leans forward and is not more than 4 ins. from the front bars. Fill in the space at the back with fire-clay. See that your register is open not more than one-fourth of its full capacity. If you have no register, partially close the chimney opening with another fire-brick. Fill in the front space beneath the grate with a movable piece of metal. If you cannot do this, put a small fire-tile in the bottom of the grate.'

It must be remembered, however, that the above efficiencies are only obtainable under the most favourable conditions ensuring the proper combustion of the fuel.

Heat Losses.

When a room is maintained at a higher temperature than the surrounding air, there is always a loss of heat through the windows, walls, air-change, etc. Modern practice demands that these losses shall be estimated as accurately as possible; a few of the most useful factors concerned are given below:—

Brick wall 12″ thick	. .	0·30	B.Th.U. loss per F. deg. diff. per sq. ft. per hour	
Brick wall 18″ thick	. .	0·24	,, ,, ,, ,,	
Without plaster 12″ thick	.	0·34	,, ,, ,, ,,	
Without plaster 18″ thick	.	0·26	,, ,, ,, ,,	
Concrete wall 4″ thick	. .	0·53	,, ,, ,, ,,	
Concrete wall 8″ thick	. .	0·40	,, ,, ,, ,,	
Single window	. . .	1·06	,, ,, ,, ,,	
Double window	. . .	0·76	,, ,, ,, ,,	
Air	. . . . .	0·019	,, ,, ,, cu. ft. ,,	

Thus with an inside temperature of 70° F. and an outside temperature of 30° F., the loss per sq. ft. per hour in the case of a single window would be

$$1{\cdot}06 \times (70 - 32) = 40\text{B.Th.U.}$$

The following are some of the channels through which heat may be lost:—

Gases of high calorific value escaping to the chimney unburnt.
Flue gases passing away at high temperatures.
By radiation and convection from uncovered pipes and fittings in Boiler House.
,, ,, ,, ,, ,, in Trenches.
,, ,, ,, ,, ,, in Basements.
,, ,, ,, ,, ,, on Roof.
Steam blowing away into atmosphere.
Condense water cooling in collecting well, etc.
Leakage from, and the cooling of air in, ducts where heated at intake.
Heated air passing away without doing any useful work.
Excessive heating of rooms.
Normal heating of rooms where not in use.
Leakage from air flues.

Reliable comparison of existing work can only be made after exhaustive tests, as owing to conditions varying so much, comparison can easily be misleading, a careful theoretical test balance would be more reliable than an incomplete one of existing conditions.

Care in design at every point to prevent waste, makes a very important whole in large buildings.

Economy.

The most economical system is that which wastes the least heat and costs the least in attendance and upkeep, providing the initial cost is reasonable.

Direct radiation plants are the most economical. Systems where the air is fully heated at the intake and distributed by ducts throughout the building will obviously have a rather high fuel consumption.

As a distributing medium, hot water comes the first, except where exhaust steam is available; there is not a great deal of difference between water and steam, providing that each is the best of its kind.

Cost of Heating.

The warming of the air costs much more than moving it; where it would take 2*d.* to move 1,000,000 cubic feet, it would cost 12·5*d.* to heat it from 30° to 60° F.

Heating Systems.

The heating medium may be either water, steam, or gas. In the case of water and steam these may be distributed in various ways, as follows:—

Water	Low pressure gravity circulation.
	Forced or induced circulation by accelerators.
	Various automatic induced.
Low-pressure steam.	Condense through traps (live-steam or exhaust-steam).
	Vacuum systems.
	Automatic vapour systems.

Heating by Hot Water.

Gravity Circulation.

For installations not exceeding, say, 5,000 sq. ft. of radiating surface, where upkeep and attention are serious items, and the building is suitable, this system is very satisfactory, and, if no exhaust steam is available, for economy it cannot be beaten.

Arrangements of Circulation.

The two-pipe method was at one time nearly universal. The single pipe has taken its place to a great extent, but a combination of the two is most general. The 'drop' system gives a very rapid circulation.

The following points require to be borne in mind:—Short circuits, dips and air-pockets, size and lengths of mains.

Size of Mains.

The first thing to decide is the maximum drop in temperature to be allowed between the flow and return; a small drop is desirable, but not always practicable, 20° may be taken as a standard. The following formula agrees very well with practice:—

$$U = \left[\left(16{\cdot}353 \frac{\left(H - \frac{S_1 H}{S_2} \right) 12D}{L} + 0{\cdot}00665 \right)^{\frac{1}{2}} - 0{\cdot}0816 \right] D^2 1224F,$$

where,

H = height of circulation in feet; S_1 = specific gravity of water in flow pipe; S_2 = specific gravity of water in return pipe; L = equivalent length of pipe in feet (bend. say. 12 diameters); D = diameter of pipe in inches; F = drop between flow and return in degrees; U = British Thermal Units per hour.

The rapidity of circulation in vertical pipes often increases at a greater rate, owing to bubbles of steam forming.

The above formula gives B.Th.U., but the curves on the following diagram, fig. 1, are in sq. ft. of radiation, calculated on an average of 160 B.Th.U. per ft. of radiating surface.

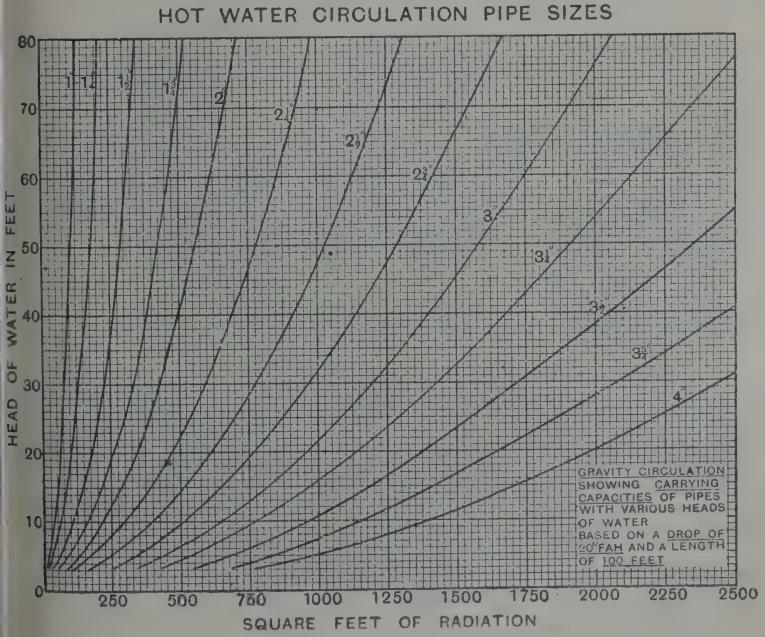

FIG. 1.

For short pipes, such as connections to radiators, a liberal allowance should be made to make up for velocity loss at entry and through connections; these have a considerable effect, so that apart from having a well-designed scheme, it is necessary to have an intelligent fitter.

TABLE OF FACTORS FOR DIFFERENT LENGTHS OF MAINS.

Length of Main. Ft.	Factor.
50	1·5000
100	1·0000
150	0·8125
200	0·7000
250	0·6125
300	0·5375
350	0·4875
400	0·4500
450	0·4375
500	0·3875

For different lengths of mains, multiply the heating surface from fig. 1 by the factor given.

CIRCULATION BY ACCELERATORS.

In large buildings where the radiation is extensive and at many different levels, pumps may be employed to circulate the water; this allows of smaller mains, owing to the higher velocities obtained. The piping may be arranged either on the one-pipe or two-pipe system. With the one-pipe, practically only the mains are under the influence of the pump, though there is a little pull on the branches, due to the loss of head on the main between the point where the flow is taken off and the return back.

The number of gallons of water required to supply the heat can be ascertained as follows:—

$$G = \frac{U}{10D},$$

where,

G = number of gallons per hour; U = heat loss in B.Th.U.; D = drop in temperature (F.° allowed between flow and return.

The size of mains depends upon their length, the number of gallons, and the maximum loss of head due to friction to be allowed. A fair velocity in the mains is from 60 to 200 ft. per min., according to the size and length, arranging for the frictional head not to exceed about 20 ft.; this is a point that should be carefully watched, as a contractor may cut down the size of mains to save initial cost, but, as a result, increasing the cost of upkeep.

The friction head and power required may be calculated in the usual manner for cold water.

There are several special types of accelerators on the market, though most centrifugal pumps are suitable, also drum or other pumps may be used if desired.

AUTOMATIC INDUCED CIRCULATION.

Where power is available, a simple accelerator is to be preferred; but there are conditions where an automatic arrangement is an advantage. These utilise the power of steam in some form, either by condensation, a partial vacuum being formed which exerts a powerful pull on the water in the returns, or by the pressure being utilised to lift water from one tank to another at a higher level, the water returning through the circuits by gravity; a separate steam boiler is not always needed, steam being formed in connection with the water boiler.

Apart from the particular apparatus for producing the motive power, the heating system is the same as any other low-pressure system.

Low Pressure Steam Heating.

GRAVITY RETURN.

In this system the condense water finds its way back to the boiler by gravity. The steam may be distributed to the radiators by either the one- or the two-pipe system.

In single-pipe work the steam in the mains travels in the direction of the condense water, but in the risers and branches they meet (except in the drop system), and when starting the heat, noise is created. Where absence of noise is essential at all times, the two-pipe system is preferable; with this arrangement there are two pipes to each radiator, the condense pipes are carried down into a wet return or fitted with an automatic water-seal at the outlet to the radiator.

Size of Pipe.

The size of pipe to supply a given amount of heat at a given point depends upon the length initial pressure, and the maximum loss of pressure to be allowed.

Taking the known formula for steam, and modifying the exponent and value of P, we get the following:—

$$U = \left(\frac{WDP^5}{L\left(1 + \frac{3{\cdot}6}{D}\right)} \right)^{\frac{1}{2}} 10^6,$$

where,

U = British Thermal Units per hour; W = weight of a cubic foot of steam; P = loss of pressure in inches of water; D = diameter of pipe in inches; L = length of pipe in feet.

The results shown in Fig. 2 have been worked out for about 1·3 lb. initial gauge pressure and ins. water gauge drop.

For one-pipe work, multiply B.Th.U. by 0·5.

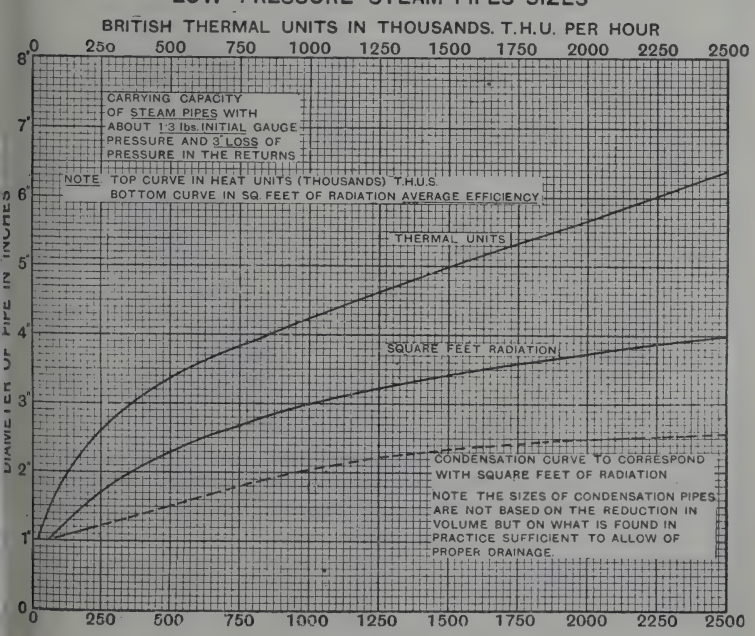

Fig. 2.

Pipe Sizes for Vapour or Low Pressure Steam Systems.

For small work, and ready reference, the following tables may be used; they are based on conservative drop in pressure in all piping; care should be exercised in ascertaining length runs:—

Example.—To find size of main required under the following conditions:—Length of ru 150 ft., with six 90° elbows, and carrying 250 sq. ft. of radiation. From Table I a 2 in. ma approx. is required. Under 2 in. on Table II it is found that each 90° elbow has the equivale resistance of 5 ft. of pipe, or 30 ft. for the six elbows. This makes the total length of pipe equ valent to 180 ft. Checking back under 200 ft. of run (the nearest length to the run desired), is found that a 2 in. pipe will carry 325 sq. ft. of radiation.

Riser sizes are determined in the same way. All lengths to be measured from the boiler.

TABLE I.—MAIN AND RISER SIZES.

Main Sizes.						Riser Sizes.				
	Length of Run in feet.						Length of Run in feet.

Minimum Weights of Pipes (fig. 4).

Overall Length. Feet.	Lbs.	Lbs.	Lbs.	Lbs.	Lbs.	Lbs.	Lbs.	Lbs.
3	15	24	32	50	67	86	108	130
6	27	45	61	94	125	160	201	243
9	—	66	90	138	182	234	294	356

All sizes of low-pressure heating-pipes and fittings shall be tested by an internal hydraulic pressure of 100 lbs. per square inch, applied for at least 2 minutes. While under pressure each pipe and fitting shall be struck all over with a hand hammer weighing $\frac{1}{4}$ lb.

* By permission of the British Engineering Standards Association.

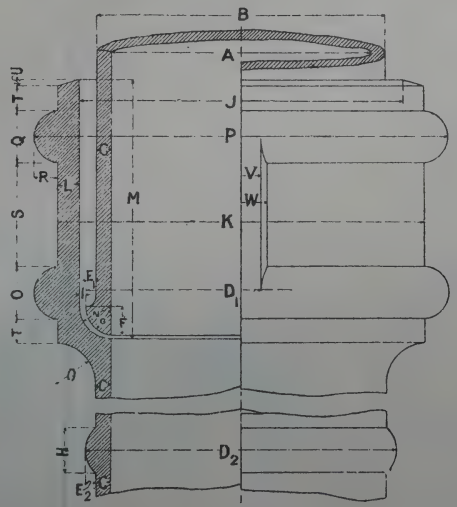

FIG. 3.

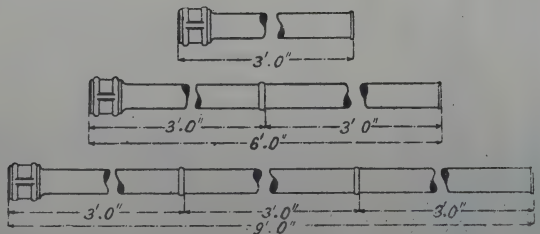

FIG. 4.

Vacuum System.

One of the objections to the ordinary gravity steam work is the difficulty of displacing the air in the radiators, and controlling the heat; this may be overcome by attaching a system of piping to the air valves connected to a small exhausting pump, which draws away the air and forms a partial vacuum; another way is to attach all the condense mains to a pump which will exhaust the air and draw away the condense water, this method is known as the 'Vacuum System.'

The piping is much the same as an ordinary gravity arrangement, except that the mains are rather smaller, and the condense pipes much smaller.

Owing to the thorough circulation of steam, the radiating surface has a high efficiency per sq. ft. per degree difference. It should be noted, however, that this does not materially affect the fuel efficiency.

The success of a vacuum system depends to a large extent on the proper working of the valves which are fixed on the radiators, or wherever condense water is likely to collect.

Plenum System.

'Plenum' is the name given to the system where the air is dealt with at the intake, tempered, washed, heated, and blown into the various rooms in such a quantity as to provide ventilation and make good the heat losses, the size of outlets being so proportioned as to allow of a slight pressure in the building, hence the name 'Plenum.'

The inlets may be from 8 to 10 ft. above the floor level, outlets at floor level on the same side of the room, the initial velocity of the air carrying it across the room, some of it cooling and gradually falling on the way—an extra outlet at ceiling level is advisable, especially if gas is the illuminant. Two ducts are necessary, one for hot and one for tempered or cold air.

NOTE.—Any system where the air is propelled into a building and maintained at a higher pressure than the atmosphere is a Plenum system, though the name is usually associated with downward methods of ventilation only.

Centrifugal fans are the most suitable, as the resistance of the heaters is considerable, apart from the ducts.

There are several special makes, including the multivane types, for which a much higher efficiency is claimed.

For economy a fan should be chosen that will pass the amount of air just running at a suitable speed to overcome the resistance, as the power rises as the cube of the speed, while the output is only directly as the speed.

Heating by Exhaust Steam.

The use of exhaust steam for heating and other purposes such as drying, hot-water supplies, etc., is to be recommended wherever possible, as the adoption of this system enables the latent heat in the steam to be used, whereas this cannot possibly be used for the production of power, and the extension of this system would render many small and inefficient power plants at present in existence more efficient.

For instance, the Technical Advisor to the Coal Controller states that the average thermal efficiency of steam-driven electric power plants at the present time is only 8½ per cent., whereas, if sufficient demand for heat can be found to enable the exhaust steam to be used for heating purposes, etc., the thermal efficiency of these plants might be increased to something like 60 per cent.

The exhaust steam can be either taken direct from the engines and conveyed without back pressure, for considerable distances, by the adoption of a modern vacuum system, or alternatively it can be used to heat water in calorifiers and the water pumped round to the various points where heat is required.

In many institutions, hotels, etc., it is found that there is practically no difference in the coal consumption whether the power is purchased from outside or generated on the premises, as there is a demand for heat all the year round which can be met by the exhaust steam from the power plant, so that the extension of this system to general domestic heating from the existing small power plants would enable these small power plants to run at a greater efficiency than any large condensing plant.

The utilisation of exhaust steam for heating when, as is too frequently the case, there is a back pressure on the engine—does not always result in economy. For assume that at a large works offices are to be warmed, requiring 800 sq. ft. of radiation, which offices are at such a distance from the main engine that a back pressure of 8 to 10 lbs. is required to force the circulation, the engine being 200 h.p. cutting off automatically at one-third of its stroke; the effect of the back pressure in this case would be to decrease the range of expansion to approximately one-half stroke, and presuming the initial pressure to be 80 lbs., and the consumption at one-third stroke to be 25·7 lbs. weight of steam per h.p. per hour, the consumption would be increased to 29 lbs. per h.p. hour, or a total for the 200 h.p., of 200 × 3·3 (the latter figure being the difference in the con-

sumption without and with back pressure) = 660 lbs. of steam per hour. Now as the amount of radiation mentioned would require, at 8 to 10 lbs. pressure, less than 300 lbs. per hour, there is, so far from being an economy, a loss of over 360 lbs. of steam per hour as the result of using the exhaust steam under such conditions of back pressure. Only when it is used without back pressure will the full economy be derivable from the utilisation of exhaust steam for heating.

One square foot of radiation will give off about 250 heat units an hour. One pound of steam an hour will supply about 4 square feet of radiation. A rough-and-ready rule for finding the radiation that may be supplied by an engine is to multiply the horse-power of the engine by 131.

When estimating on exhaust-steam heating, with non-condensing engines, the steam consumption for each indicated horse-power an hour will be about as follows :—

Engine.	Total.	Available for Heating.
Compound automatic	20 lbs.	18 lbs.
Simple Corliss	30 lbs.	27 lbs.
Simple throttling	40 lbs.	36 lbs.
Simple automatic, single valve	35 lbs.	31 lbs.

When exhaust steam is employed as the heating medium it is necessary to extract the grease by means of a separator, so placed as to intercept the grease before the steam enters the heating main. It is also necessary to have an outlet to the atmosphere which should be closed by a valve weighted to open at a pressure of ¼ lb. above the atmosphere, so as not to cause any back pressure. So low a pressure can, however, only be used for circulation when a vacuum return line is maintained, as in the vacuum system, for unless the air is first exhausted from the apparatus, a definite pressure is required to force it out through the air valves. With a vacuum return line no air valves are required on the radiation, and no foul air from the radiators discharged into the rooms.

In steam heating, the temperature depends on the pressure of steam in accordance with the figures given in the following table :—

TABLE OF THE PROPERTIES OF SATURATED STEAM.

Boilers.

If plenty of draught is available, a boiler with a liberal amount of secondary flues and small grate area may be chosen; if the draught is small, one with less flue resistance would be more suitable. It should be of such a design as to allow of proper combustion in the fire-pot, free circulation in the waterways, the lighting, feeding, and ash doors to be well fitted, so as to stop an inrush of air at undesirable points; the general design to allow of clinkering and flue cleaning to be carried out with a minimum of trouble. The catalogue rating should give the number of B.Th.U. given off with a *six hours' firing interval*; *this should be taken from test, not based upon square feet of boiler heating surface, the value of which varies very much with different makes.* The *fuel efficiency* should be stated, and should *not be less than* 60 *per cent.* On testing a well-known sectional boiler, the highest efficiency was found to be at seven hours' firing interval (78 per cent. evaporative test), with a slight drop to four hours (due to loss from high flue temperature) and a quick drop to ten hours (due to incomplete combustion). While in power boilers combustion has received a deal of attention, heating boilers have been neglected in this respect.

Approximate Minimum Size of Boiler House for Different Sized Heating Installations.

Amount of Radiation in Feet Super.	Dimensions of Boiler House.*		
1,000	9 ft. long	5 ft. wide	7 ft. 6 ins. high
2,500	11 ft. „	6 ft. „	7 ft. 6 ins. „
5,000	13 ft. „	9 ft. „	8 ft. „
10,000	14 ft. „	13 ft. „	9 ft. „
20,000	18 ft. „	16 ft. 6 ins. „	10 ft. „
50,000	18 ft. „	32 ft. „	10 ft. „

* Exclusive of fuel space.

If hot water supply, boiler, etc., are required, extra space must be allowed.

Approximate Size of Chimney for Various Sized Installations.

Radiation in feet super.	1,000	2,500	5,000	10,000	20,000	50,000
Size of chimney in inches	9×9	14×9	14×14	21×18	24×24	36×36

The Cochran Hot-Water Boiler.

This boiler (*Cochran & Co., Annan, Limited*) is manufactured in twenty-two sizes corresponding to the range of standard boilers, the essential difference being the considerably reduced height, diameter for diameter, as compared with the steam units.

The 8 ft. 6 in. diameter boiler can be limited in height to 14 ft. should headroom considerations necessitate this.

The range of duties vary from 390,000 to 6,500,000 B.Th.U. per hour reckoned on a two-hourly stoking interval in the case of boilers with two fireholes.

These boilers retain all the constructional advantages of the standard Cochran boiler.* They can be supplied for a working pressure of 100 lbs. per sq. in. (*i.e.* for use with a head of 230 feet of water), and, with reasonable care, will last indefinitely. The Cochran boiler manufacturers claim that as a hot-water unit the arrangement occupies less floor space than any other type of boiler. As compared with cast-iron sectional types, the high efficiency and durability of this boiler are important considerations, while the prices are below those of steel sectional and wrought welded boilers. Also, owing to the entire absence of brickwork setting, etc., they are cheaper than the built-in types of boiler, a feature of importance in large heating schemes.

A fire-box of any capacity can be supplied, but the standard sizes are fully equal to all normal requirements, and to meet 'banked' conditions two fire-doors can be provided.

With regard to the outlet connection at the top of the boiler, it is necessary to submit details of the available head-room and size of flow-pipe in the system, to enable a suitable flanged bend to be supplied. The diameter of the return pipe must also be indicated, in order that a suitable flange connection may be provided. In the absence of this information standard flow and return connections would be supplied; these are made with flanges to B.S. Table No. 1.

The smoke-box of the Cochran hot-water boiler enables the funnel to be taken off in any desired direction relative to an existing system of flues in the building, thus keeping within the height of the boiler, in cases where headroom is limited.

* See p. 1646.

Fuel.

The average calorific value per pound of fuel may be calculated at 12,000 B.Th.U., but of this it is only possible to obtain in the boiler an actual efficiency of 70 to 75 per cent. In other words, 8,000 B.Th.U. would represent the heat available from the boiler per pound of fuel burnt, the coal being of an average quality.

SIZE OF MINIMUM FUEL SPACE REQUIRED FOR VARIOUS SIZES OF HEATING INSTALLATIONS ON A BASIS OF ONE MONTH'S SUPPLY.

Radiation in feet super . . .	1,000	2,500	5,000	10,000	20,000	50,000
Fuel space in cubic feet . . .	500	1,000	2,000	3,800	7,600	19,000

FUEL SPACE REQUIRED FOR GENERAL OFFICE BUILDINGS.

Cubic feet of fuel space = cubic contents of building $\times \frac{6 \cdot 45}{1,000}$.

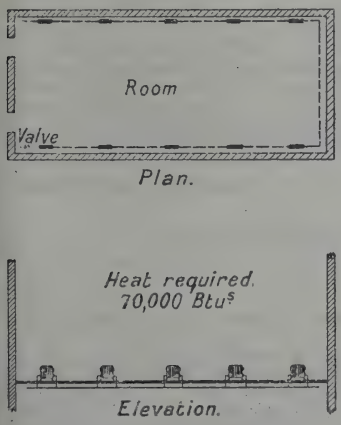
Radiators.

RADIATING SURFACE.

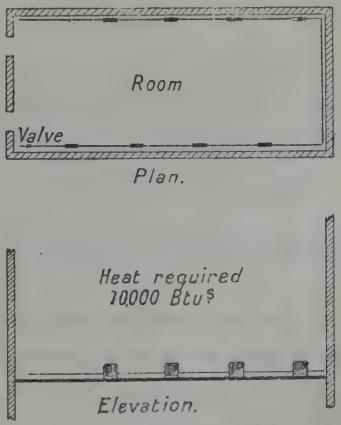
Vertical Loop Radiators are mostly used. Their efficiency varies with the design and size. They should be plain, smooth, and the loops so spaced as to allow of every part being easily cleaned.

Where it is permissible for the pipe supplying the radiators to be above the floor, the initial cost is considerably reduced, as will be seen from fig. 6; this is an important point often lost sight of in considering the cost of a heating installation.

The amount of radiating surface will vary according to the class of surface and its temperature.



Pipes below floor: cost £98.
FIG. 5.



Pipes above floor: cost £73.
FIG. 6.

A recent test carried out by the Research Committee of the Institution of Heating and Ventilating Engineers has shown that a safe figure for modern radiation is 150 B.Th.U. per sq. ft., with a difference of 100° F. between the temperature of the water and surrounding air.

The above figures show the advantage of having the pipe above the floor where permissible.
Note.—Prices fair competitive basis (January 1928).

It has also been proved that the emission varies as the 1·3 power of the temperature difference between the heating medium and surrounding air. This is a very useful factor, as within reasonable limits obtained in general heating the transmission can be found at any given temperature difference.

It will be seen, therefore, that the amount of radiation in any room will vary considerably according to the temperature of the heating medium; for instance, if a room has a heat loss of 100,000 B.Th.U., the amount of surface required for providing a temperature of 60° F. would be:—

Steam at 212° F.	390 square feet of radiation.
Water at 185° F.	510 „ „ „ „
Water at 160° F.	660 „ „ „ „

Fig. 7 shows the variation needed for drop in temperature on a hot water circuit, each room being supposed to have exactly the same heat loss.

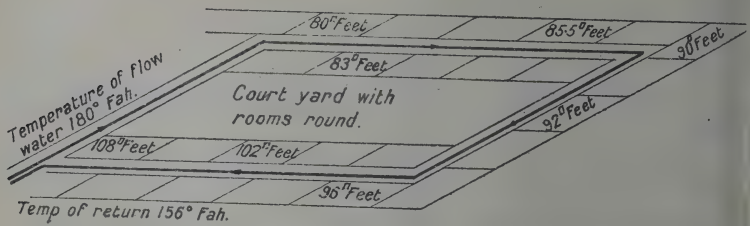


FIG. 7.

The above figure represents a number of rooms which are supplied with a hot water ring main, either forced or gravity circulation; each of the rooms is supposed *to have the same heat loss* (about 14,800 B.Th.U.); the figures show the amount of double col. radiation required, and show the *increase in surface required* due to drop in temperature of the water in main. A total drop of 24 degrees is taken. The chief object of this diagram is to draw attention to a fact which is often given secondary consideration.

NOTE.—It is good practice if possible to arrange the circulations so that the hottest water is at the coldest side of building.

In indirect radiators, the B.Th.U. vary approximately as the square root of the velocity of air passing over the heated surfaces.

AMOUNT OF RADIATION SURFACE REQUIRED IN ROOMS OF AN AVERAGE HOUSE.

Type of Room.	Radiation in Feet Super. per 1,000 Cub. Ft. (To supplement domestic fires.)	Radiation in Feet Super. per 1,000 Cub. Ft. (Without fires in rooms.)
Corner room with large exposed wall and window surface	12	20
Less exposed room	9	15
Passage	—	20
Bedrooms	10	16

Radiating Surface required for Different Classes of Buildings, and Cost of Heating.

Type of Building. (Taking the total cube.)	Average Heating Surface in Feet Super. per 1,000.	Approximate Cost of Heating per 1,000 Cubic Feet.
Churches	12	75 shillings
Hospitals	20	140 "
Block of offices	15	98 "
Public buildings	12	84 "
Factories	7 to 10	47 "
Residences	12	84 "
Small detached residences	15	105 "
Retail shops, etc.	8	52 "

The amounts given include the surface in mains for average work.

These costs, which are based upon present-day prices (January 1928), do not include builders' work, cutting away, making good, etc.

For country work, add 10 per cent. to cover additional allowance to workmen, travelling, and incidental expenses.

Where all pipes are concealed, add 25 per cent.

Approximate Heating Surface required for Horticultural Heating.

Type of House.	Approx. surface in feet super per 1,000 cubic feet.
Houses requiring to be kept at a temperature above 35° in order to prevent frost entering	16
Peach and similar Houses	27
Greenhouses	40
Tomatoes. Vines, etc.	60
Forcing Pits	130

Table of Radiation.

Height of Radiator in Ins.		46	38	36	32	30	26	24	23	20	18
Type.	Length of One Section. Ins.	Heating Surface per Section in Ft. Super.									
Single Column	3	—	3	—	2½	—	2	—	1⅔	—	—
Two Columns	3	5	4	—	3½	—	2⅔	—	—	—	—
Three Columns	2¾	6	5	—	4½	—	3½	—	—	—	2¼
Four Columns	3	—	8	—	6½	—	5	—	—	—	3
Classic 4 Column	2	—	—	3	—	2½	—	2	—	—	1½
Classic 6 Column	2	—	—	4½	—	3¾	—	3	—	—	2¼

To find the space necessary for radiators, multiply the above figures by the number of sections required, adding 8 ins. in length for valve, elbow, union, and bushing.

WIDTH OF RADIATORS AT FEET.

	Ins.		Ins.
Single column	5½	Three columns	10½
Two columns	8⅜	Four „	11

The kind of metal, and the thickness of the latter, of which the radiator is made, has little effect upon the heat transmission, provided the radiator is not painted.

Some recent experiments have proved that painting may affect the radiation as much as 28 %.

The white enamels give rather a better effect (103 %) than a plain unpainted surface (100 %). The ordinary white paints give about 100 %, the greens dropping to 96 %. Copper and aluminium bronzes are the worst, 72 %.

The *thickness of the coat* makes very little difference.

THE WESTINGHOUSE PATENT STEAM RADIATOR.

The Westinghouse Patent Radiator shown in fig. 8 was designed to overcome the disadvantages formerly attendant on the use of steam for heating purposes. Steam enters the radiator at A and passes through the opening in the valve seat B into a distribution pipe C, in the upper side of which a small hole is drilled opposite each column. It then passes up each column as shown

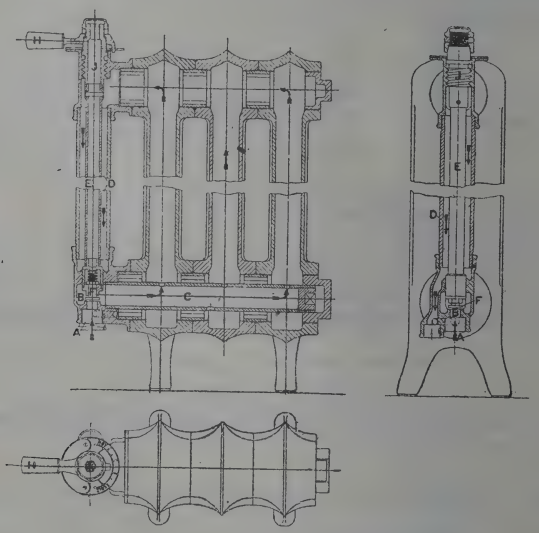

FIG. 8.—The Westinghouse Patent Radiator.

by the arrows and into tube D. This tube contains another tube E of metal with a high coefficient of expansion, and when it reaches a temperature of about 210° F. or any other lower temperature to which it is set, expands and closes the valve F, thus shutting off steam until the temperature is slightly reduced, when the valve again opens.

The temperature of the radiator can be varied as desired up to the maximum by moving the handle H which, owing to the screwed socket J, moves the tube E and valve F nearer to, or farther

from its seat B, and thus causes the valve to close at a lower or higher temperature as desired. The temperature of the radiator can never exceed 212° F., as the steam inlet is restricted by the valve while the outlet is fully open to the return line, and the steam is entirely therefore condensed in the radiator, only water escaping to the return line. It will therefore be seen that the temperature of the radiator does not depend on the pressure of the steam supply, nor is it affected by the distance of the radiator from the source of supply.

Contract Temperatures and their Equivalents.

(Direct Radiation.)

These, which are of considerable interest to architects and engineers, have been the subject of considerable controversy. Some years ago a Committee of the American Institute of Heating and Ventilating Engineers reported on the subject; in 1903 Mr. Walter Jones gave a paper before the English Institute. Professor Allen's paper on 'The Coefficient of Heat Transmission in Cast Iron Radiation,' June 1908, is one of the most modern.

The expression $$\frac{t_2 - t_3}{t_2 - t} = \frac{t_3 - t_5}{t_5 - t_4}$$

is considerably in error, *even taking into consideration the different coefficients of transmission, extra losses due to increased air changes, etc.* In the discussion on Professor Allan's paper, Mr. C. B. Thompson said he had recently made some tests, but could not get more than 105° F. inside, with an outside temperature of 85° F. and surface that gave 70° inside when 0° outside.

The following empirical formula is found to agree closely with *actual tests* :—

$$t = [t_1^{12} - t_2^{12} + t_3^{12}]^{\frac{1}{12}}$$

where,

t_1 = contract inside absolute temperature F.;
t_2 = contract outside " "
t_3 = existing " " "
t_4 = estimated inside " "

The curves shown in fig. 9 are worked out from the above formula for reference under different contract conditions.

The time factor is an important one, as will be seen from fig. 10, which is from an actual test of a large public building warmed by steam-heated accelerated hot water. The upper curve shows the inside temperature and the lower curve the outside temperature.

Automatic Regulation of Heating Apparatus.

It is very desirable that with hot water or steam installations some arrangement should be made for automatic regulation of the room temperatures independent as far as possible of the human element. The chief drawbacks to regulation of this description have been—firstly, expense; secondly, complicated apparatus requiring skilled attention to ensure the proper efficiency of same. Recently, however, the tendency has been for each room to have its independent automatic regulation instead of being part of a complete system of automatic apparatus, and this tendency has gradually evolved a simpler form of apparatus, some of which are being used with great success at the present time.

In addition to the independent room regulation it is also desirable to have further regulation of the boiler independently, not based on the water temperature of the boiler, but on the variation of the outside temperature; and experience proves that in this country it is preferable to regulate the boiler by means of the outside temperature than by the temperature inside the building.

The Thermutator automatic boiler damper regulator combined with outdoor thermostat, made by *The Drayton Regulator and Instrument Co., Ltd., West Drayton*, for hot-water boilers, operates the draught door in accordance with variation of outdoor temperature. The boiler thermostat is arranged above the boiler in a tube, and can be isolated by closing a cock.

The 'Drayton' A.M. Regulator.

(The Drayton Regulator and Instrument Co., Ltd., West Drayton.)

This regulator, fig. 11, is operated by water pressure. The pilot valve is actuated by metal expansion.

The fig. shows the regulator applied to the control of a water heater, but in place of the diaphragm operated valve, diaphragm operated dampers or other devices may be substituted.

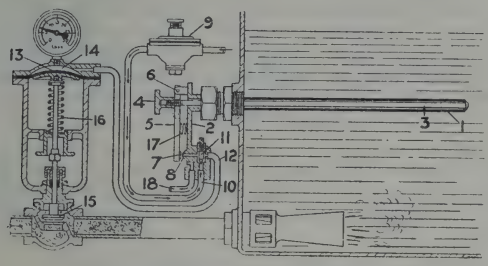

FIG. 11.—'Drayton' A.M. Regulator.

A modified form of this type of regulator is also made for the control of room temperatures.

The great power obtained by the 'Drayton' pilot valve system enables the largest valves or dampers to be operated without loss of accuracy.

HOT WATER SUPPLY.

Hot water supply can be divided into three classes:—

1. Domestic hot water supply suitable for ordinary houses.
2. Hot water supply for institutions, hotels, etc.
3. For industrial work.

Domestic Hot Water Supply.

The general apparatus for this purpose in an ordinary house is a boiler behind the range, a cylinder in a convenient position, and a supply tank. Points which should have attention are as follows:—

Boiler and its flues should be so fixed in the range as to be easily cleaned; also it should have an emptying tap.
Cylinder should be as near the boiler as possible, so as to ensure an easy circulation.
Feed tank should be in an accessible position, and protected from frost.

The fuel efficiency of a range boiler is low, and experience proves that even in quite small houses an independent boiler is more economical. It will be found that the major portion of the fuel used in a range is taken by the boiler, and not by the ovens required for cooking.

Institutions and Hotels Hot Water Supply.

For this class of work where steam is not required for other purposes, independent hot water boilers are the most economical. The type of boiler will depend on the nature of the water; where the water is hard it is desirable to have the boiler of as simple a form as possible, with ample provision for cleaning out, a bolted top being very desirable in this connection. In some cases it may be found necessary to either soften the water or put in a system of secondary heating, in which case the water in the boiler is circulated through a coil which heats the water in a secondary manner. Where the water is not hard, the sectional boilers 'Bower-Barffed' have proved very successful and highly efficient. In domestic supply it is desirable that the cylinder, which would usually be of a horizontal type with dome ends, should be as near the boiler as

possible; from this cylinder, secondary circulations of considerable length may be taken to the various parts of the building, to supply the different fitments. In arranging hot water supply circulations and draw-offs, it must always be remembered that where there is a branch off the circulation, and the tap on the end of that branch is open, water will flow both ways, both from the flow direction and from the return direction, the return, therefore, should connect to the cylinder at a high point. This is most important, and many failures have been due to neglect of this necessary arrangement.

In many cases steam is required, especially in institutions and hotels, for different purposes such as cooking, etc.; in such cases, instead of having a separate hot water supply boiler, it is desirable to heat the water by steam. This is done by means of a calorifier; in principle it is simply a coil of steam pipe enclosed in a vessel of water, the steam being condensed and the latent heat of the same being conveyed through the coil to the water outside. This system also lends itself to thermostatic control. For this class of work it is very necessary that the pipe from the supply tank to the storage cylinder be of ample size. In some installations of a large size it is desirable to do away with the supply tank and simply keep the installation full by means of a pump, the pump automatically starting on a tap being opened. This system has many advantages but is not so well known as the usual one of having a supply tank.

Westinghouse Lavatory Water Heater.

Where a supply of steam is available this heater affords a convenient means of obtaining hot water instantly without the use of hot-water tanks.

Referring to fig. 12, steam enters by a pipe connection, which is in direct communication with chamber B. Cold water enters by a pipe connection which communicates directly with chamber D. Valves E and F are kept closed by springs G and H, when the handle J is in the 'OFF' position.

When the handle is moved to position 'COLD,' the bell crank K pushes open valve F, and cold water only flows through the passage L to the space between the tubes N and M, and thence by pipe connection O to the lavatory basin.

On moving the handle further over to the position 'HOT,' the steam valve E is also opened by the bell crank K pushing against its stem, and steam then flows by passage P to the interior of tube N, and thence to the atmosphere by pipe connection R.

The heat of the steam being transmitted through the walls of the tube N to the water as it flows down the narrow space between the tubes M and N, the water is hot by the time it reaches the outlet N, while the steam in tube N is partially condensed before issuing from outlet R. The spring S returns the handle to the 'OFF' position.

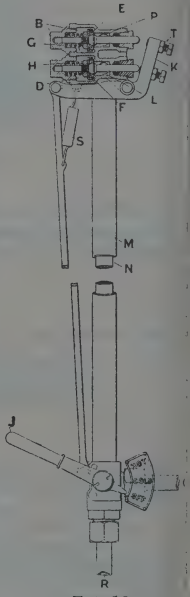

FIG. 12.

Method of ascertaining Heat necessary for a given Supply of Hot Water.

The basis of the calculations is that one British Thermal Unit will raise the temperature of 1 lb. of water 1° F. This figure varies a little according to the temperature of the water, but the variation is so small that for the purpose of hot water supply calculation, it may be neglected.

On the above basis we get the following simple formula—

$$B = \frac{G \times 10 \times T}{H} + R,$$

where,

B = British Thermal Units per hour;
G = gallons of water;
T = degrees it is required to raise the temperature of water;
H = time in hours allowed for obtaining the required temperature;
R = radiation losses from pipes and cylinder, per hour.

Example.

It is required to raise 100 gallons of water from 40° to 150° F. in 2 hours then

$$B = \frac{100 \times 10 \times 110}{2} = 55{,}000.$$

With regard to radiation losses, we may assume the cylinder and pipes loss to be, say, a mean of 10,000 B.Th.U. per hour ; the total B.Th.U. per hour would then be

$$55{,}000 + 10{,}000 = 65{,}000.$$

It is assumed that the circulating pipes and cylinder would be covered with non-conducting material to conserve the heat.

A boiler will transmit on an average from 2,500 to 7,000 B.Th.U. per hour per foot of boiler surface, 2,500 being for secondary flue surface, and 7,000 for fume firepot surface. An average of 5,000 may be taken for an ordinary independent boiler with normal firing. A tube in a well-designed calorifier will transmit from, say,8,000 B.Th.U. per foot at 1 lb. pressure to 37,000 B.Th.U. at 50 lbs. pressure. The pressure of the water surrounding the tubes has quite an appreciable effect on transmission, apart from the temperature of the steam.

Apart from the usual hot water supply in a hospital, a special sterilised supply is required for surgical work in the operating theatres ; steam is generally used for this purpose, and the water is heated to sterilised temperature, or generally boiled, and the apparatus so arranged that the sterilised water does not come into contact with unsterilised water or air before it is delivered at the taps for the use of the surgeon.

Hot Water by Gas.

Gas is often used for the purpose of heating water, especially in small installations, and a very usual application of this, in an ordinary size house, is to connect up the gas-heating boiler to the circulating pipes, so that during the summer when the range is not required (the gas-cooker being used for cooking) the gas-heater boiler can be used when desired. Apart from the geysers, etc., the systems of heating the water are arranged in a general manner, as regards arrangements of circulation, etc. The amount of gas necessary is on the basis of the calorific value per cubic foot. The average calorific value of town gas is, say, about 500 B.Th.U. per cubic foot. Assuming the boilers of the heaters to have an efficiency of 80 per cent., this would mean that 400 B.Th.U. of the 500 should be actually transmitted to the water, so that, taking the amount of water to be heated as mentioned above, namely, 100 gals., to be raised 110°, which requires 65,000 B.Th.U., this divided by 400 will give 162·50 cub. ft. of gas necessary.

Heating Water by Electricity.

For domestic uses, surgical work, industrial, and other purposes, a method of heating water by electricity is very handy ; but there is a disadvantage, it is very expensive if a very large quantity of water is required ; this will be seen from the following :—

The electrical Board of Trade Unit contains 3,411 B.Th.U., and as the efficiency of electrical heating apparatus is very high, it may be considered that 3,000 B.Th.U. of the 3,411 would be transmitted to the water. Again, taking the quantity mentioned above, the amount of electricity required would be 65,000 B.Th.U. divided by 3,000, which gives us 21·7 units of electricity required. With regard to the type of heater, one very handy form, and one easily replaced, is the ' Immersion Heater.'

Industrial Hot Water Supply.

Hot water is required in a great many industries, and the method of heating the same is generally similar to the foregoing methods, although, very often waste heat of the furnaces in various industrial processes can be utilised for heating the boiler. For some requirements such as bottling, washing, etc., where it is desirable to have the water under considerable pressure the closed pump system lends itself to this class of work. (*J. Roger Preston.*)

Heating and Drying.

Not infrequently rooms and chambers are found provided only with steam pipes, which have to do duty at night and in the day time in order to keep pace with requirements. Such rooms

are very bad drying places, and very slow into the bargain because the essential air current is lacking, and failure attends the introduction of a fan under these circumstances, owing to the influx of cold air following its use and lowering the temperature. To be effective the air must be raised to the required temperature before distribution and should act as a vehicle for the conveyance of the heat to and about the drying rooms or chambers.

To derive the maximum benefit from the use of exhaust steam, drying rooms of considerable size should have two or more divisions, as by this means operations may commence in one section soon after starting the engine, and conveniently proceed so that the operators may work in the cool part and finish up within a period of time to coincide with shutting off steam.

The proper temperature to effect rapid and perfect drying varies considerably, and depends upon the nature and texture of the material to be treated. Provided, however, the warm air current is fairly proportioned, then mechanical drying will considerably enhance the value and quality of the work, and vastly expedite and cheapen the process.

SECTION XXXVIII

PART II

VENTILATION.

(Revised by J. Roger Preston, Vice-President of the Institution of Heating and Ventilating Engineers.)

Amount of Air necessary for Ventilation.

Whenever possible, it is desirable to provide 3,000 cubic feet of air per hour per person for halls, theatres, etc. Owing to the restrictions of cost and building construction, the sizes of the ducts necessary for this amount are rarely attainable, so a more usual figure is 1,800 cubic feet of air per hour per person. The L.C.C. regulations give 1,000 cubic feet of air per hour per person as the minimum amount of air required in buildings licensed by them.

Assuming a building in which there are, say, 3,000 people, and taking the L.C.C. requirements of 1,000 cubic feet per hour, this means about 830 cubic feet of air per second. The velocity permissible in the ducts will depend to some extent on their length, but 15 to 20 feet per second may be taken as a good maximum average. This means that the inlet and distributing ducts should have an area of not less than 50 square feet. As a streamline section must be maintained, it follows that where a change of direction in a duct of this size takes place, considerable space is taken up, and unless provision has been made for same, difficulties may be encountered. Steelwork is often a very important factor, especially in connection with the vertical subsidiary ducts, and is very difficult to modify; this trouble can only be avoided by close collaboration between the various parties concerned in the early stages of the building.

A very important point to bear in mind in the general planning is to allow plenty of room for the engineering equipment and to arrange that every part shall be easily accessible to the engineer in control of the plant. Experience proves that this is most essential, but is often overlooked or sidetracked to make room for something else.

The aim should be to make a system of ventilation as noiseless as possible, though this may not be necessary in industrial work. A good deal can be done by attention to details, but the fundumental factor is to keep low velocities, enabling the fans to run at slow speed, thus saving power. The space required and the initial cost will probably be more than for a system having high velocities, but it cannot be too strongly emphasised that in good class work *low air velocities and slow-running fans are essential to successful ventilation.*

The foregoing statement applies whatever system is adopted, and it must be remembered that *high air velocities and high-speed fans are a source of trouble and expense*, however attractive it may appear at the time to install small trunks that are easily adapted to the building.

Distribution of Air.

Convection currents are a most important factor in ventilation, and should be closely studied. This can conveniently be done either by balanced mica vanes or by blowing air through HCl and NH_4OH, the vapours so formed causing, when mixed, a dense white smoke (not heated). When these convection currents are known it can then be decided whether natural or mechanical methods will be required to give satisfactory ventilation and the best positions for the introduction of the air.

If natural ventilation is utilised, the air should be introduced at low level, preferably behind radiators, and allowed to find its way out at ceiling level.

Three methods of mechanical ventilation are employed, the particular method to be used depending on circumstances.

(*a*) *Mechanical extract* only. Inlets are provided at a low level, preferably behind radiators, the air being extracted by means of a fan at high level. This method is commonly employed in halls seating under 1,000 people, and similar buildings.

(*b*) *Mechanical inlet* only. Inlets are provided at a low level or about 6 feet above floor level. A common distribution is one-third of the total area of gratings at low level and two-thirds at 6 feet up. Outlets are provided through the walls at high level or through the ceiling. This method is employed when fresh air from outside is not otherwise obtainable.

(*c*) *Both mechanical inlet and extract.* The extracts should be as (*a*) and the inlets as (*b*). This method is used for large halls and particularly difficult problems, such as basements and enclosed rooms. The amount of air extracted mechanically is usually 75 per cent. of the air introduced by the inlet fan.

Where circumstances will allow, it is often found an advantage to arrange the distributing ducts, inlets, and outlets in such a way that the direction of air currents in the room can be reversed for different atmospheric conditions and temperatures.

Air-Filtering, Washing and Conditioning.

It is always desirable and frequently essential that the air should be as free from dust and impurities as possible. This dust can be removed by filters and air washers. There are several types of air filters obtainable, but they can be divided into two main groups:

(*a*) *Dry filters.*—These consist of a series of perforated plates arranged so that the perforations are staggered, the plates being covered with a sheet of wadding on the up-stream side for the better collection of the dust. The filtering effect is dependent on the number of plates. To clean, the filter unit is detached from its frame and shaken.

(*b*) *Viscous fluid filters.*—In these, the air passes over a series of plates or troughs coated with a viscous fluid to which the dust adheres. To clean, the filter unit is washed in strong soda water, dried, and then dipped in the viscous fluid and allowed to drain before replacing.

Air washers commonly used consist of a series of fine sprays through which water is pumped, the air mixing thoroughly with this finely divided spray, afterwards passing over a series of eliminator plates which collect the surplus water together with the dust.

The use of dry or viscous filters removes the dust without altering the temperature or humidity of the air, while the air washer varies both the temperature and humidity, thus making it unsuitable for certain purposes although it is frequently advantageous, especially when applied to the ventilation of halls and theatres.

The endeavour to produce a pleasant and healthy atmosphere inside at all times of the year whatever the outside conditions may be, has received a good deal of attention of late years, and in this connection a term *Effective Temperature* has been brought into use. The 'Effective Temperature' is influenced by three factors: (1) Dry bulb temperature; (2) Wet bulb temperature; and (3) Velocity of the air. The most suitable 'Effective Temperature' may vary, according to circumstances, from 60° to 70° F. If, however, it were 90° F. outside, it would be very unwise and actually uncomfortable for people to go into a temperature of, say, 60° F. or even 70° F. In this case, the reduction of the dry bulb temperature by about 10° F. together with a perceptible air movement, would probably give rise to a marked degree of comfort.

Air Cooling.

Air can be cooled by an air washer, but the relative humidity will always rise. In a washer using recirculated water, the heat content will not be substantially changed although a certain cooling effect can be obtained with a consequent rise in relative humidity. The wet bulb temperature is unaffected by this method, so that the cooling is limited by the initial wet bulb temperature and will in practice always be a few degrees above this. Actually it will be found that the dry bulb temperature can be reduced to, say, 75 per cent. of the difference between the wet and dry bulb temperatures.

When artesian well water or some other water having a temperature of 52° F. is obtainable the air can be cooled to about 57° F. with a consequent reduction in the vapour contents of the air should the initial dew-point be above 57° F., which is most probable in hot weather. The air will then be saturated.

When air is required with a lower temperature than can be obtained by the air washer refrigeration will have to be employed. Cooling air is far more expensive than heating, owing to the condensation of the moisture in the air. For general ventilation, the air may be cooled from 10° F. to 15° F., but for industrial purposes, when it is required to have complete control over the relative humidity and temperature, it is usual to cool the air to 35° F. The amount of brine to be circulated should be calculated on a drop of 3° F. The specific heat of brine may be taken as 0·82° F., and in calculating the heat required for the reduction in temperature the condensation of the vapour must not be forgotten. The heat in British thermal units required divided by 12,000, will give the size of plant required in tons of refrigeration per day of 24 hours.

The heat exchange in cooling or heating air over a given range of temperature is not materially different, provided the dew-point is not reached. Should, however, the initial humidity be such that the dew-point is reached in the cooling, another very important factor is introduced, a portion

of the aqueous vapour being condensed and giving up its latent heat in the process. The British thermal units involved in the heat exchange may be ascertained by the following, which is accurate enough for all practical purposes and shows the various points involved :

$$U = \overbrace{L_C (W_1 - W_2)}^{\text{SECTION A.}} + \overbrace{S_v(T_1 - T_2) W_1}^{\text{SECTION B.}} + \overbrace{S_a (T_1 - T_2)}^{\text{SECTION C.}},$$

where,

T_1 = Initial dry bulb temperature;
T_2 = final ,, ,, ,,
W_1 = weight of aqueous vapour per lb. of air at initial temperature T_1;
W_2 = ,, ,, ,, ,, final ,, T_2;
L_C = mean latent heat of vaporisation or condensation at initial dew-point, and T_2;
S_v = specific heat of vapour;
S_a = specific heat of air;
U = B.Th.U.'s to cool 1 lb. of air from T_1 to T_2;

Basic figures to be taken for this and other equations :

S_v = specific heat of aqueous vapour = 0·44;
S_a = ,, ,, air = 0·2415 *;
L_C = latent heat of vaporisation varies from 1073·4 B.Th.U.'s per lb. ar 32° F. to 1052·3 B.Th.U.'s per lb. at 70° F.

Section A is the heat required to be extracted to condense the water vapour.

Section B is the heat required to be extracted to reduce the temperature of the water-vapour contents of the air and is so small that it can usually be neglected.

Section C is the heat required to be extracted to cool the air from T_1 to T_2.

Velocities of Air Flow for Mechanical Ventilation and Flow of Air Through Ducts.

Where silence is essential, the velocities of flow of air in ducts must be kept low, the ideal velocity being from 10 to 15 feet per second, and on no account exceeding 20 feet per second. For factory work speeds up to 30 feet per second are allowable, but this velocity should not be exceeded. In general, the outlets to the rooms (if at low level) should be of such an area that the air issues at a velocity of from 3 to 5 feet per second, as such velocities do not give rise to a sensation of draught. In certain circumstances, however, such as during hot weather, it may be found desirable to direct a flow of air across a room at a velocity of 10 to 15 feet per second, this movement giving a feeling of coolness. (See 'Effective Temperature' p. 2510.) The following table gives the permissible velocities for different parts of the ventilation system. The lower figure refers to ventilation where silence is desired, and the higher gives the maximum permissible for factories, etc.

Fresh air intake	500 to 800 ft. per min.	Main ducts	800 to 1,200 ft. per min.
Heating battery	800 ,, 1,500 ,, ,,	Branch ducts	600 ,, 900 ,, ,,
Filter	150 ,, 350 ,, ,,	Registers	180 ,, 300 ,, ,,
Washer	300 ,, 500 ,, ,,		

The flow of air through a building resembles an electrical circuit, the inlets, outlets, and ducts acting as the resistance, and absorbing some of the aeromotive force. *To ensure an even flow in various ducts requires considerable care*; the resistance must be low, as the initial force in ventilation is small, usually equal to about 0·25 ins. of water, or 17 pneumatic units. In natural ventilation it is much less than this.

In order to obtain an even distribution of air throughout the system, the design of the ducts is very important. Changes in direction and section should be as gradual as possible, particular care being taken to avoid sudden changes. The finish of the ducts should always be of the best, as roughness and irregularities increase immensely the resistance to the flow of air. The ducts are usually made of galvanised iron or in builders' work. When made by the builders the ducts should be lined with glazed bricks, or, if this is too expensive, finished with Keene's cement or some similar hard, smooth finish. It is always advisable to whitewash the latter, as the presence of dust is then easily noticed and more likely to be removed. The importance of the foregoing will be appreciated when it is realised that in mechanical ventilation where silence is essential the fan should not work against a resistance exceeding 1in. W.G. and in other general work it is advisable not to exceed 2in. W.G., except for dust extraction and similar industrial processes.

* 0·238 was at one time the accepted figure for specific heat of air and will be found in many textbooks, but 0·2415, or sometimes 0·2400, is now accepted as the more correct value.

RESISTANCE OF FLOW OF AIR PER 100 LINEAL FEET OF CIRCULAR GALVANIZED IRON TRUNKING.

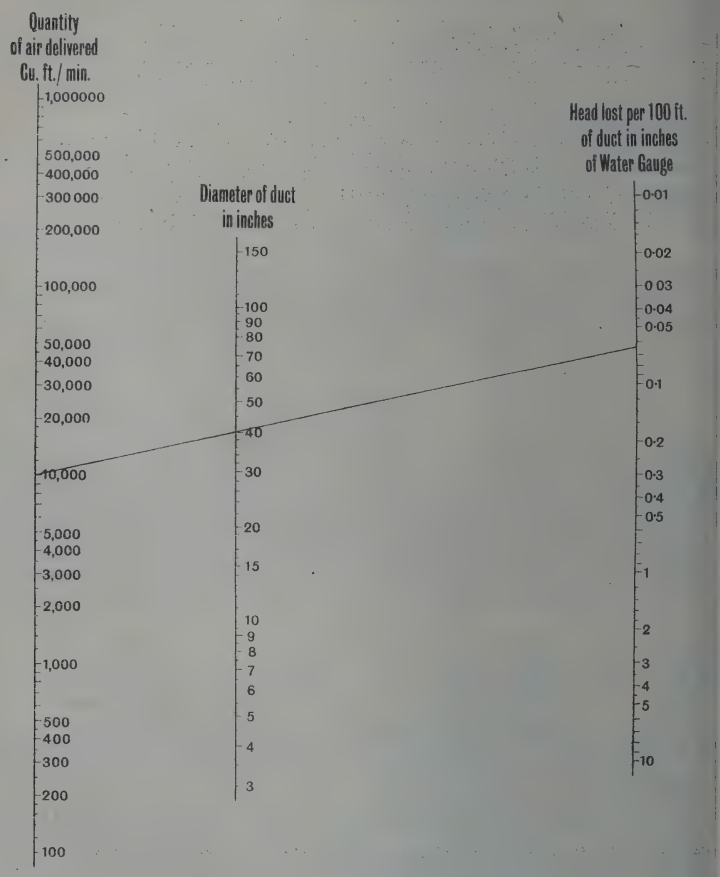

FIG. 1.

EXAMPLE: To find the loss of head in a 40-in. diam. duct carrying 10,000 cu. ft. of air per minute, lay a straight edge as shown connecting 10,000 cu. ft./min. and 40-in. diam., reading the loss of head 0·064 ins., W.G. per 100 ft., on the right.

. There is yet a need for research work in connection with the flow of air in ducts, but the ollowing will be found a useful formula for the flow of air through galvanised iron pipes :

$$C = 39d^{2\cdot5} \Big/ \left(\frac{L}{H}\right)^{\frac{1}{2}}$$

here,

C = cubic feet of air per minute ; L = length of pipe in feet ;
d = diameter of pipe in inches ; H = drop of pressure in inches of water.

The values derived from this formula are shown more conveniently in fig. 1.

For resistance in ducts of other materials than galvanised iron, multiply the result obtained rom the diagram or by the above formula by the following factors :

Smooth concrete . . . . 1·5 Brickwork . . . . . 2·0

When arriving at the total resistance in a duct, allowance must be made for bends and loss ue to entry and egress at registers. The loss of a sharp elbow varies from 30 to 60 diameters. smooth bend 5 diameters and a usual register 80 diameters.

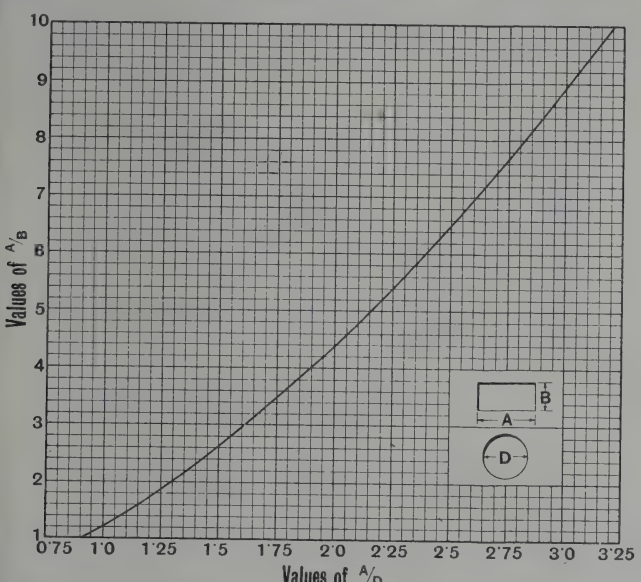

FIG. 2.

Diagram for obtaining equivalent Diameter of Round Duct carrying the same amount of air for the same loss as a Rectangular Duct.

To obtain the total head against which the fan has to work, the velocity head must be added the resistance in the duct ; this is obtained from the following formula :

$$h = \frac{6D \cdot v^2}{gk}$$

ere,

v = velocity in ft. per sec. ; h = velocity head in W.G. ;
g = 32·2 ; D = density of air at temperature required
k = density of water = 62·4 ; = 0·0749 for dry air at 70° F.

All the above is based on circular pipes. In the case of rectangular pipes, find the equivalent

circular pipe to give equal discharge for equal resistance from the following formula, and then use fig. 1 to find the resistance to flow :

$$D = \sqrt[5]{3{\cdot}25 \frac{A^3B^3}{A + B}},$$

where

A = long side of rectangular pipe ; B = short side of rectangular pipe ; D = dia. of equivalent round pipe.

This equivalent diameter can conveniently be found by means of fig. 2.

Movement of Air by Fans.

The choosing of a suitable fan is a most important factor in any scheme of mechanical ventilation.

There are two distinct types of fans used for this work : the propeller and centrifugal, one similar to a ship's propeller, and the other more like a paddle wheel.

A propeller is a very efficient and useful fan if used in the proper way, that is, either with free inlet and outlet, as, for instance, when fixed in a window or wall without any trunking attached, or with short trunking of ample size, causing very little resistance head.

In the average building a fan must run at a low speed to avoid noise. At this speed the efficiency of a propeller fan falls off very considerably against resistance, as will be seen from

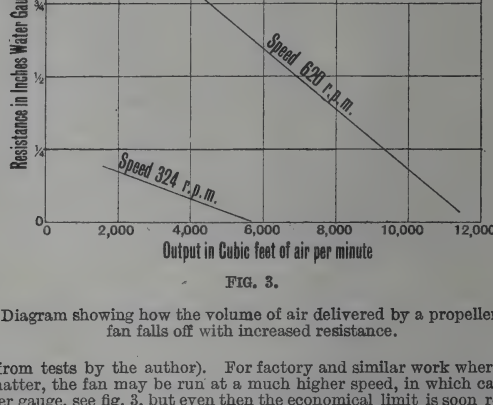

FIG. 3.

Diagram showing how the volume of air delivered by a propeller fan falls off with increased resistance.

fig. 3 (plotted from tests by the author). For factory and similar work where noise and extra power do not matter, the fan may be run at a much higher speed, in which case it can be used at a higher water gauge, see fig. 3, but even then the economical limit is soon reached. It must be remembered also that as the quantity of air decreases, due to resistance, the power increases.

The centrifugal fan can be used up to any reasonable pressure, but for general ventilation where absence of noise and economy of power is desired, it is good practice not to exceed about 1 in. total head (resistance head + velocity head), the filters, heaters, ducts, etc., being designed accordingly.

When the resistance is increased, the amount of air falls—so also does the power taken. At a lesser resistance the volume of air increases—so also does the power.

Should a centrifugal fan and motor be designed for a given resistance, and then the resistance turns out to be less than expected, there is a great danger of the motor being overloaded, unless a specially large one has been installed. To meet this condition, a special fan has recently been put on the market, and the author's experience of this fan so far has been very satisfactory.

The Fan Standardisation Committee of the Institution af Heating and Ventilating Engineers after devoting some five or six years to the study of the subject, has recently issued a very comprehensive report on the testing of fans, terms to be used, and method of cataloguing, etc. to which the reader is referred.

* 'Report of the Fan Standardisation Committee, 1927' (price 2/6). Office of the Institution 12 Russell Square, London, W.C. 1.

Movement of Air other than by Fans.

As the air in a flue such as a chimney or outlet duct from a warmed room is at a higher temperature than the outside atmosphere, its density is less, and the tendency is for it to rise. The resulting velocity of flow varies within wide limits, but is theoretically given by :

$$V = 480 \sqrt{\frac{h\,(T - t)}{t - 460}}$$

where,

V = velocity of air in feet per minute ; T = temperature of heated air °F ;
h = height of flue in feet ; t = outside temperature °F.

The actual velocity is considerably lower in practice, and the result from the above formula should be multiplied by 0·25 to 0·6, according to size, shape, and materials.

In addition to the movement of air due to difference of temperature, the wind has a considerable aspirating effect on a properly designed ventilator.

The following data are taken from some tables in the ' Robertson Ventilation Data Book ' :*

Temperature Difference, Fahrenheit.	Height of Ventilator above intake.	Wind Velocity in Miles per hour. 2	6	10

Heating units such as gas jets, electric heating, steam or hot water coils, are sometimes used for the purpose of causing an up-draught. These should never be used if any other method is available, as they are very inefficient and costly in up-keep, costing, in the case of steam coils for example, on an average six times that of moving air by fans. Blowers and Exhausters.

Sturtevant Blowers and Exhausters.

(Sturtevant Engineering Co. Ltd., London, E.C. 4.)

The design of a fan depends upon the pressure against which it has to discharge. A blower designed for low pressure is not suitable for high, and *vice versâ*. Figs. 4 to 10 show various types.

Fig. 4.

Air Propeller.

For moving large volumes of air from one part to another where the resistance is low. Used for ventilating and exhausting.

Multivane Centrifugal Fan.

For moving large volumes of air against 1 to 4 ins. water gauge. Fan wheel has shallow blades with corrugations to prevent lateral slip. Used for ventilating, drying apparatus, mechanical draught for boilers, etc.

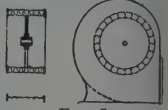

Fig. 5.

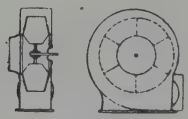

Fig. 6.

Steel Plate Cased Centrifugal Fan.

For air pressures up to 8 or 10 ins. water gauge. The square section steel plate casing is used, but the wheel has deeper blades and side plates (shrouds). Used for dust exhausting, conveying, etc.

Cast Iron Casing Fan.

For obtaining higher pressures up to 15 ins. water gauge, the casing must be more carefully designed and preferably made in cast iron. The wheel is narrower and deeper than that for lower pressures. Used for blowing forges, furnaces, etc.

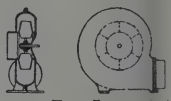

Fig. 7.

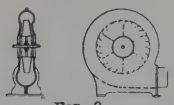

Fig. 8.

High Pressure Fans.

For blowing cupolas, etc., requiring air pressures from 12 to 30 in water gauge. The scroll must be most carefully designed and the wheel have a greater number of blades. For sizes and capacities of this fan see page 2656.

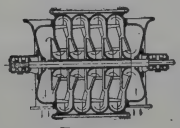

Fig. 9.

Multistage Fans.

For blowing and exhausting air at pressures up to 3 to 4 lbs. per square inch.

Rotary Blowers.

These are used for many duties, for blowing and exhausting air or gases where pressures up to 5 lbs. per square inch are required.

Fig. 10.

Power Variation of a Blower at Constant Speed.

Propeller Fans.—Power rises slightly with pressure; volume decreases rapidly as pressure rises.

Centrifugal Fans.—Power increases as pressure falls, and volume increases.

Rotary Blowers.—Power increases directly with pressure, volume remaining about constant.

The 'Wing' Fan.

(F. W. Potter & Co., Phipp St., Great Eastern St., London, E.C. 2.)

The general arrangement of the blades of the Wing fan or air propeller is shown by fig. 11. t is claimed that the Wing fan, for a given amount of power, will move a greater volume of air han any other pattern, owing to the shape, angle, and curvature of the blades, and the method f securing them to the central boss. It has been found that an angle of 27½° to 30° is the best ll-round angle for combined output and efficiency.

A distinctive and useful feature of the fan is the adjustability of the angle of the blades, the atter being readily set to any angle. If desired, the direction of the air current may be reversed, his reversal of the air current being effected without impairing the efficiency of the fan.

The blades of the Wing fan are usually made of steel, but for certain purposes they are made f copper, aluminium, or Muntz metal.

The fan wheel is mounted on a spindle running in bearings lined with best quality Babbitt netal, and the framing is constructed of cast iron or wrought iron according to circumstances.

The Wing fan is manufactured in all sizes, arranged with pulley for belt drive, or direct coupled o electric motor.

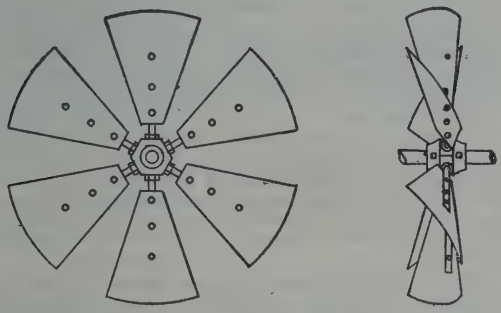

Fig. 11.

Economy of Power.—Where conditions permit of the choice between a propeller type and a entrifugal type of fan, the following rules are useful :—

(*a*) For open ventilation use propeller fans.

(*b*) Make main air duct same diameter as fan, or larger, avoiding acute or sharp angle bends.

(*c*) When small ducts and sharp bends are unavoidable use centrifugal fans.

(*d*) Use large fans at as low a speed as will overcome whatever resistance is in the way of free assage of air.

Example.—A 10 ft. Wing fan at 90 revs. per min. delivers 71,000 cu. ft. of air per min., absorbing ·2 h.p.

A 5 ft. Wing fan at 720 revs. per min. delivers 71,000 cu. ft. of air per min., absorbing 19·2 h.p. Volume for volume, therefore, the smaller fan uses 16 times the power absorbed by the larger fan.

(*e*) Use two fans of the same diameter at low speed instead of one at double the speed.

Example.—A 48 in. Wing fan at 600 revs. per min. delivers 30,200 cu. ft. of air per min., absorbing 3·6 h.p.

Two 48 in. Wing fans at 300 revs. per min. deliver 30,200 cu. ft. of air per min., absorbing ·9 h.p. ogether.

Volume for volume, therefore, one fan uses four times the power absorbed by two fans.

MOTORS FOR DRIVING VENTILATING FANS.

Too much cannot be said regarding the location of the motor. On account of the natu of the work it is frequently necessary to place the machine in an out-of-the-way place, althoug this does not necessarily mean that it must be in an inaccessible location. If it is so place that it is difficult to care for, it will probably be neglected, with the result that the service w be impaired and the maintenance charge will be high. The placing of a motor in an inco venient place because nothing else will go there, is false economy generally, and results i dissatisfaction. The question of motor efficiency in regard to fan drives is an important o and involves two factors—the efficiency of the motor when operating under normal speed, an the efficiency at other than normal speeds. Although the latter is, to some extent, influenc by inherent characteristics of the motor, the largest factor is the method of control, especial with direct-current motors. If, on account of its lower cost, a motor is selected, where adjus able speed is required, that will, when operating at normal speed, drive the fan at the maximu required speed, and it is necessary to operate for considerable periods at reduced speed, lo efficiency will result.

The cost of the power lost in the armature external resistance will usually pay a handson dividend on the additional capital required to install a motor and controller that, at norm speed, will drive the fan at the lowest speed required and beyond this point adjust the spe by field control.

The horse-power required to drive a centrifugal fan can be estimated from the followi formula:

$$HP = \frac{5{\cdot}2 \times Q \times WG}{33{,}000 \times E}$$

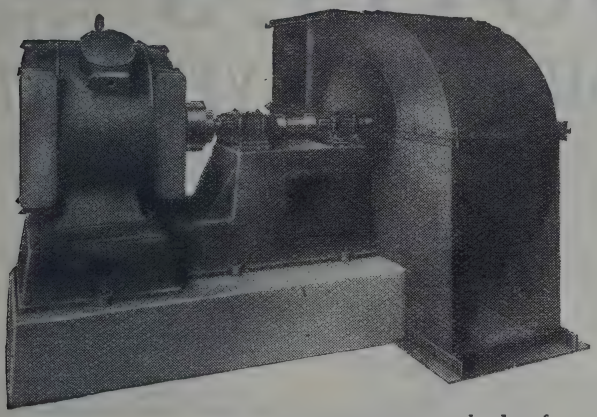
where,

HP = horse-power of motor; Q = cubic feet of air per minute; WG = pressure of a in inches by water gauge; E = efficiency of fan, which is approximately 0·5 for a steel plate fa 0·65 for Sirocco, and 0·45 for cone type.

The following mathematical relations are theoretically true for all centrifugal fans: Volun of air delivered varies as the speed; pressure of air delivered varies as the square of the spee horse-power required varies as the cube of the speed. Hence a fan, which, when operated 100 r.p.m. delivers 8,000 cub. ft. of air at ½ oz. pressure, requires 2 h.p., will, when operat at 200 r.p.m., deliver 16,000 cub. ft. of air at 2-oz. pressure and will require 16 h.p. It is ther fore necessary, in selecting a motor for driving a fan, to figure the horse-power requirements the maximum speed of the fan.

Reduction of the area of the inlet or discharge of a centrifugal fan will reduce the pow required, whereas increasing the area of either will increase the power. Disc fans produce relatively low pressure, and it is customary to figure their output on a basis of velocity. T relations between volume, speed, and horse-power for centrifugal fans hold good for disc fan However, if the outlet of a disc fan is restricted, the pressure and the power required increas and with a totally closed outlet the power needed is almost double that with an unrestricte outlet. (*'Power.'*)

Air in Harness



Below are some of the Sturtevant methods of applying air for all purposes.

Dust and Refuse Collecting,
Heating and Ventilating,
Air Filters, Wet, Dry and Viscous,
Drying,
Timber Seasoning,
Smoke, Steam and Fume Removal,
Vacuum Cleaning,

Pneumatic Despatch Tubes,
Mechanical Draught,
Cinder Eliminating Fans,
Crushing, Grinding,
Screening Machinery,
Elevators and Conveyors,
Fans and Blowers for all purposes.

Ventilators.

The Boyle 'Air-Pump' Ventilator.

In the latest patented forms of Boyle's patent 'air-pump' ventilators the wind, striking gainst and being deflected by curved vanes causes a suction effect which draws out the foul ir and effects perfect ventilation. One form of the 'air-pump' ventilator, known as the *ridge* entilator, is shown by fig. 12. The wind blows through the openings, and in passing over he curved plates causes a strong upward draught.

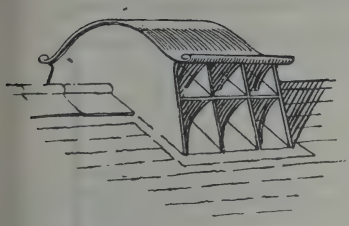

Fig. 12.

No. 175.

Fig. 13.

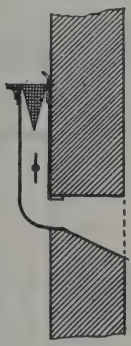

Fig. 14.

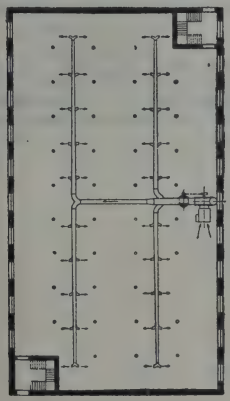
In the 'air-pump' ventilator (fig. 13) the curved vanes are set vertically.

For the necessary admission of fresh air to take the place of that extracted by the ventilator, Boyle's Air-Inlet Bracket, shown by fig. 14, may be adopted. The top of the inlet should be bout 5 ft. 9 ins. above the level of the floor, and the outside opening should be covered with n iron grating.

The Plenum System.

This system (*The Sturtevant Engineering Co. Ltd.*) is well adapted for the economical warming and ventilation of workshops, large halls, theatres, and other large buildings. The



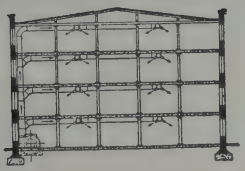


Fig. 15.

apparatus consists of a fan which draws in fresh air, delivering it through a heater where it is warmed to the required temperature, and then evenly distributed through a series of ducts to

every part of the building. The fan is usually of the steel-plate type driven by belt from line shafting, steam engine, or electric motor; the heater is built up with a nest of pipes for use with live or exhaust steam, hot water, furnace gases, etc. Ducts for distributing the air are constructed of galvanised sheet steel, masonry, wood, or other materials, and may be built in the walls or floors, or suspended from the roof or walls.

The system ensures even distribution of warmth throughout the whole building with proper ventilation. In the summer the heater can be eliminated and fresh air distributed throughout the buildings. Workshops can be quickly warmed up in the morning before work is commenced, by recirculating the air. The fan and heater can be installed at one central

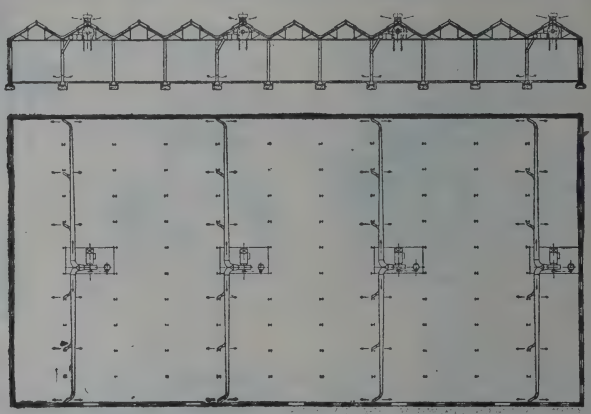

FIG. 16.

point either inside the building or outside, and they are under complete control of one man who can regulate the temperature of the air supply as required.

Two types of buildings equipped with this system are shown by figs. 15 and 16. Fig. 15 illustrates a building of several storeys, in which the apparatus is placed in the basement, one air main being carried up through the building with overhead horizontal distributing pipes on each floor.

Fig. 16 shows a large workshop of considerable height, in which the apparatus is divided into four units in order to keep down the size of the air piping. The sets of apparatus are placed out of the way in the roof, the air being distributed by overhead pipes and discharged at floor level through downtake pipes arranged alongside the column. An alternative arrangement would be to install one set of apparatus and connect it with each of the pipe mains.

SECTION XXXVIII

PART III

LIGHTING

(Revised by W. J. Jones, M.Sc., A.M.I.E.E.)

Terms in Illumination.

International Candle.—This is the unit of light intensity standardised in Great Britain, the United States of America, and France (*Bougie decimale*), and is one-tenth the intensity of the standard 10 candle Harcourt Pentane lamp burning under specific conditions of barometric pressure and humidity.

The relationship between the International Candle and other units is shown in the following table :

Unit.	Is Equivalent to :		
	International Candle.	Hefner Candle.	Carcel Unit.
One International Candle .	1·0	1·1	0·104
One Hefner Candle . .	0·9	1·0	0·09375
One Carcel Unit . .	9·6	10·66	1·0

Mean Horizontal Candle Power.—As the intensity of a light source generally varies in all directions, this term is employed to denote the mean candle power obtained by averaging the candle-power readings measured in all directions on a plane passing through the centre of the light source and perpendicular to its axis.

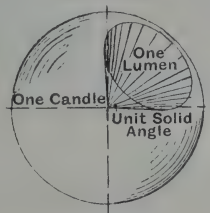

FIG. 1.

Mean Spherical Candle Power (M.S.C.P.).—This is the mean of the candle powers measured in all directions.

Lumen.—The unit denoting the quantity of light, and is the amount of light flux contained in a unit solid angle of a sphere which has a uniform light source of one candle situated at the centre. A light source of one mean spherical candle emits 4π (12·57) lumens (see fig. 1).

Foot Candle.—The unit of illumination. It corresponds to the light density on a surface. If normal to its surface, every part of an area of 1 square foot receives light of an intensity of one candle; it is said to be illuminated to a density of 1 foot candle.

If a uniform point source of light of 1 candle intensity in all directions is situated at the centre of a sphere of unit radius, every square foot of the spherical surface will be illuminated to a density of 1 foot candle. Alternatively, it may be said that if one lumen illuminates an area of 1 square foot, the average light density will be 1 foot candle.

Lux or Metre Candle.—The Continental unit of light density is analogous to our foot candle unit. When an area of 1 square metre is illuminated by one lumen, the resultant illumination is 1 lux or metre candle. It follows that 1 foot candle equals 10·76 lux.

Brightness.—The brightness of a surface is the quotient of the luminous flux intensity in a given direction divided by the area of the surface projected on a plane perpendicular to that direction.

For electric lamps and fittings this quantity is expressed in candles per square inch, while for large surfaces it is stated in candles per square foot.

Illumination.

Illumination, or the density of light received by an object, is measured in terms of foot candles, and can be shown to be directly proportional to the candle power and inversely proportional to the square of the distance from the light source, *i.e.* $I = \frac{C.P.}{D^2}$.

If a surface is oblique to the rays, $I = \frac{C.P.}{D^2} \cos \theta$, where θ is the angle subtended between the incident light and normal to the surface.

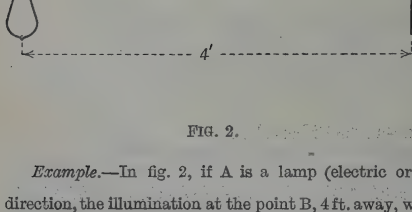

FIG. 2.

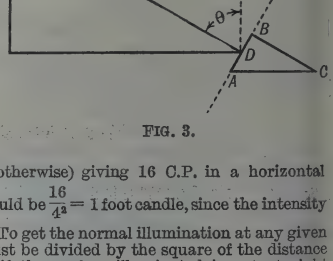

FIG. 3.

Example.—In fig. 2, if A is a lamp (electric or otherwise) giving 16 C.P. in a horizontal direction, the illumination at the point B, 4 ft. away, would be $\frac{16}{4^2} = 1$ foot candle, since the intensity of light varies inversely as the square of the distance. To get the normal illumination at any given point, the candle power in that particular direction must be divided by the square of the distance to the point illuminated. As previously explained, if the surface illuminated is not at right angles to the direction of the light, the value of the illumination obtained, as above, must be multiplied by a reduction factor, taking into account the angle at which the rays strike. A beam of light coming in the direction of OD (fig. 3) falls upon a plane AB, illuminating it with a density of 1 foot candle, then the illumination on the plane AC, which intercepts the same amount of light as AB, would be less as the light is spread over a larger surface, the reduction being in the ratio of AB to AC, which is the cosine of the angle ODF. Thus the effective illumination on any plane at a given point will be:

$$\frac{\text{C.P}}{\text{distance}^2} \times \cos \theta$$

where θ is the angle between the direction of the ray and a perpendicular to the plane considered.

BRIGHTNESS.

The brightness of an object under a given illumination depends on the amount of light reflected back by its surface, and this depends on the colour and the nature of its finish. The following table gives the approximate percentage of incident light reflected by various surfaces:

APPROXIMATE REFLECTING POWER OF SURFACES.

	Per Cent.		Per Cent.
White, rough	82	Blue paper	25
Cream	80	Wood, dirty	20
White, smooth	70	Brown paper	13
White, printed matter (grey)	60	Brown, dark	4
Wood, clean	50	Black cloth	1·5
Yellow paper (light)	40	Black velvet	0·5
Yellow, dark	30		

Photometry.

As its name implies, photometry deals with the measurement of light. By comparing the unknown light source with a known standard and using the fundamental stated above—that is, that the intensity is inversely proportional to the square of the distance—photometric readings are reduced to the measurement of lengths. In a simple photometer the standard lamp and the light source to be measured are mounted on a horizontal bench with a movable screen placed between them (see fig. 4). The screen is then moved between the lamps until both its sides appear

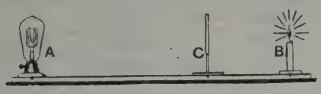

FIG. 4.

to have the same brightness. The distance AB and BC are then measured and the candle power calculated from the fact that:

$$\frac{\text{CP.A}}{\text{AC}^2} = \frac{\text{CP.B}}{\text{BC}^2} \qquad \therefore \text{CP.A} = \text{CP.B} \times \frac{\text{AC}^2}{\text{BC}^2}$$

While making such readings care must be taken that the screen is shielded from any light from other sources.

The Lummer-Brodhun photometer is a more accurate instrument in which prisms are used, so that on looking through a single eyepiece parts of both sides of the screen are seen superimposed; by this means very accurate comparisons of contrast can be made. With this instrument it is not the brightness of the surfaces that are balanced, but their contrasts, as seen in the two halves

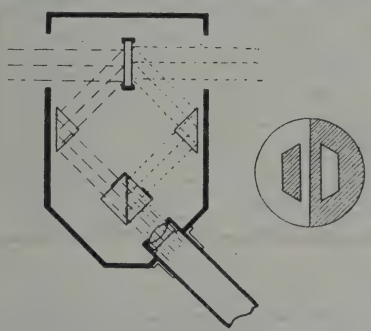

FIG. 5.

of the field. Fig. 5 shows a diagram of the Lummer-Brodhun photometer head, and also the appearance of the contrast field when viewed through the eyepiece.

The great difficulty in making candle-power measurements is the difference in the colour of various light sources, and for accurate work special means have to be adopted. One method employs colour filters, but variations in the light absorption with various lights of different complex colour composition renders this method rather unsatisfactory. Another method is to employ a flicker photometer such as the Simmance-Abady Flicker Photometer. This instrument is based on the fact that if a surface is illuminated alternately by two light sources it appears to flicker, due

both to variations in light intensity and colour. By varying the speed of the alternations it is found that the eye is more sensitive to variations of intensities than to changes of colour; so by using a critical speed of exposure the surface assumes a neutral tint only affected by flicker due to variations in intensity, and so, under these conditions, the illuminations on the screen can be balanced in the usual way.

In the actual instrument these alterations are obtained by rotating a specially shaped disc between the light sources. The rotor is provided with surfaces that slope alternately to either side, so that at any instant during the rotation the portion in front of the eyepiece is only illuminated by one lamp.

Integrating Photometer.

The sphere photometer is another form of instrument specially designed for measuring the mean spherical candle power of a light source. The apparatus consists of a large sphere with a whitened mat interior surface; the light source being placed in the centre. It can be shown that every part of the interior surface will receive the same amount of light by repeated reflections—in other words, the light is automatically averaged out; by placing a small window of diffusing glass in the side of the sphere this average intensity can be measured by the usual photometer method.

As mentioned, the effect depends on reflections in the interior, and so the window has to be carefully shielded from direct light from the source of light, also the readings must be multiplied by a constant depending on the nature of the internal surface.

Polar Curves.

Before suitable reflectors can be designed for a given source of light, or in fact before any rea idea can be formed as to the characteristics of such a source, it is necessary to know how the intensity of the lamp varies in all directions. The polar curve is a very convenient way of showing these variations, and an example is given in fig. 6. The distance scaled along any line from the

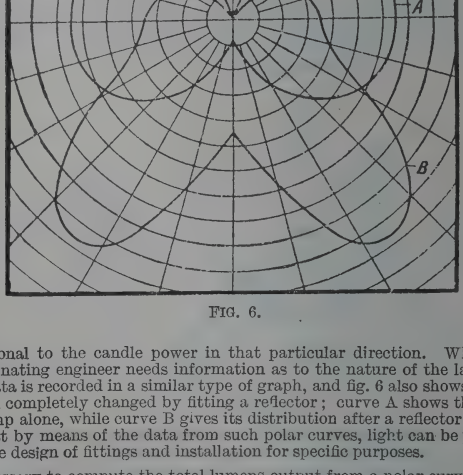

Fig. 6.

centre is proportional to the candle power in that particular direction. When handling ligh sources, the illuminating engineer needs information as to the nature of the lamp complete with reflector. This data is recorded in a similar type of graph, and fig. 6 also shows how the light dis tribution has been completely changed by fitting a reflector; curve A shows the distribution du to a particular lamp alone, while curve B gives its distribution after a reflector has been installed It will be seen that by means of the data from such polar curves, light can be properly controlled both as regards the design of fittings and installation for specific purposes.

Often it is necessary to compute the total lumens output from a polar curve, or more exactly the mean spherical candle power from which the lumens can be easily calculated. If the light source is symmetrical in its horizontal distribution and not too irregular in its vertical variations, thi can be readily performed by taking readings at what are known as the Russel Angles; the mean spherical candle power being the average of such readings. Taking the lower vertical ordinate as our zero, readings should be taken at the following angles :

Degrees.

25·8	60·0	84·3	107·5	134·4
55·6	72·5	95·7	120·0	154·2

As explained, the M.S.C.P. is the arithmetic mean of the ten readings; while if the lumen output is required this result has simply to be multiplied by 12·57.

LUMENS RATING OF GAS-FILLED LAMPS.

OTHER STANDARD TYPES OF GAS-FILLED LAMPS.

Type.	Sizes.
Opal or White Sprayed	Standard sizes up to 500 watts
Bowl Sprayed	Standard sizes up to 500 watts
Internal Frost	Standard sizes up to 100 watts
Coloured Sprayed Colours :—Red, Blue, Green, Amber, Yellow, Flame and Ivory.	Standard sizes up to 200 watts
Daylight	Standard sizes up to 500 watts

Requirements of Good Illumination.

Illumination must be acceptable to the eye. We should be able to see objects clearly and with a minimum of fatigue. To accomplish this result certain conditions must be fulfilled.

(1) There must be sufficient illumination. Since objects are seen by means of the light which they reflect, more light must be thrown on dark objects than on light ones.

(2) Intensely bright lights in the field of vision should be avoided. The iris closes somewhat in order to afford a protection from such lights, and the amount of light received from illuminated objects is thereby so reduced that they cannot be seen clearly. This accounts for the well-known dazzling effects of searchlights and of many headlights. The intrinsic brilliancy or candle power per square inch of luminous area should therefore be kept as low as possible ; it should not ordinarily be higher than 4 to 6, if the source of light is in the field of vision. Clear bulbs should certainly never be used where the filaments are continuously in view. When reflectors are used it is generally desirable to ' bowl-spray ' the lamps, *i.e.* obscure only the lower portions of the bulbs.

(3) Flickering lights should be avoided. Poorly regulated circuits, such as those having varying power loads, cause disagreeable flickering. Metal filament lamps have an inherently better regulation than carbon filament lamps.

(4) The light should have a continuous spectrum, *i.e.* one containing every colour, in order that the relative colour values of objects illuminated may be the same as when seen by daylight. For matching delicate tints, as in silk and paper mills, the light should be as white as possible, while for general illuminating purposes a ' warm ' light is best ; cold glaring lights too rich in green and blue are to be avoided. Where colour matching is important special colour matching units should be employed, but for many industrial purposes absolutely correct daylight is not required and the Daylight lamps can be used.

The size of the units is a question of design. In deciding upon the proper sizes of lamps to use, one must consider the spacing of present outlets, if building is already wired, and the location of pillars, beams, etc. In general the fewest units consistent with good distribution will be the most economical, as the total cost of outlets, fixtures, and lamps, as well as the maintenance charges, will be reduced. In many cases it is preferable to entirely rewire the premises, in order to obtain correct illumination.

REPORTS OF DEPARTMENTAL (HOME OFFICE) COMMITTEE ON LIGHTING IN FACTORIES AND WORKSHOPS.

(1915–1922.)

Third Report of the Committee, H.M. Stationery Office, Cornwall House, Stamford Street, S.E. 1.

The minimum intensity of illumination desirable for the sake of general convenience and safety in parts of the workshops where work is normally carried on, and in yards, passages, and open spaces along which people are ordinarily liable to pass, is as follows:—

2. 'Over the "working areas" of workrooms the illumination measured on a horizontal plane at floor level shall be not less than 0·25 foot-candle, without prejudice to the illumination required for the work itself.'

3. 'In all parts of iron foundries in which work is carried on or over which any person is ordinarily liable to pass, the illumination measured on a horizontal plane at floor level shall be not less than 0·4 foot-candle.'

4. 'In all parts of factories and workshops (not included under recommendation 2) over which persons employed are liable to pass, the illumination measured on a horizontal plane at floor level shall be not less than 0·1 foot-candle.'

5. 'In all open places in which persons are employed during the period between one hour after sunset and one hour before sunrise, and in any dangerous parts of the regular road or way over a yard or other space forming the approach to any place of work, the illumination on a horizontal plane at ground level shall be not less than 0·25 foot-candle.'

(*a*) 'Every light source (except one of low brightness *) within a distance of 100 feet from any person employed shall be so shaded that no part of the filament, mantle, or flame is distinguishable through the shade, unless it be so placed that the angle between the line from the eye to an unshaded part of a source and a horizontal plane is not less than 20 deg., or in the case of any person employed at a distance of 6 ft. or less from the source, not less than 30 deg.'

(*b*) 'Adequate means shall be taken, either by suitable placing or screening of the light sources, or by some other effective method, to prevent direct reflection of the light from a smooth or polished surface into the eyes of the worker.'

(*c*) 'Adequate means shall be taken to prevent the formation of shadows which interfere with the safety or efficiency of any person employed.'

(*d*) 'No light sources which flicker or undergo abrupt changes of candle-power in such manner as to interfere with the safety or efficiency of any person employed shall be used for the illumination of a factory or workshop.'

Two standards 'for fine work' and 'for very fine work' are recommended. For processes grouped in Schedule A the illumination shall not fall below three foot-candles, and for processes grouped in Schedule B shall not fall below five foot-candles.

The schedules give the class of work, and cover a large number of trades.

---

* By 'low brightness' is meant an intrinsic brilliance of not more than five candles per square inch. Examples of sources of low brightness are a batswing burner, a paraffin flame, etc., and sources of about the same brightness as these are not regarded as coming within the scope of this recommendation.

'It should be remembered that the covering of a brilliant source by a very small shade (such as a silica cup covering a high-pressure gas mantle, or a small opal globe surrounding a high-power electric source) may give this shade or globe a brightness three or four times as great as the five candles per square inch, so that it may cause considerable glare and should consequently be treated as a source of light in itself.'

Illumination Calculations.

During recent years, the 'point-to-point' system referred to in the early part of this section has been abandoned in favour of the 'lumen' method of pre-determining the lighting for an installation. This is essentially due to the fact that, owing to the accumulated experience of illuminating engineers, it has been found possible to take into consideration the contributory effects due to reflection from the ceiling and the walls. The following gives the method of procedure that is adopted generally at the present time :—

Steps in the Design of a Lighting System.

1. *Intensity of Illumination.*

The foot-candle illumination according to present standards for different classes of operations are given on p. 2400–1. These values are the minimum to be adhered to if fully satisfactory lighting is to be assured. In many circumstances, particularly where dark materials are being used, or extremely fine work carried out, higher values of illumination are desirable.

2. *Type of Lighting Unit.*

The selection of the lighting unit depends, not only on the requirements of the work, but in some measure on the construction of the room and the colour of the ceiling and walls. For instance, it would be undesirable to install totally indirect lighting equipment where the ceilings are very dark. The table on p. 2402 gives information as to whether a fitting is suitable from the point of view of glare, reflected glare, efficiency, etc., and the choice of a particular fitting would depend as to which of these factors are the more important. For instance, in an office the criteria would rank as follows in importance :—

1. Direct glare must be a minimum.
2. Reflected glare must be minimum.
3. Shadows should be absent.
4. Efficiency is desirable upon the horizontal plane.
5. Maintenance is next in order of importance.
6. Vertical illumination is least important.

On the other hand, where lamps are to be hung above a crane in the foundry, the order of importance would be :—

1. Efficiency based upon the horizontal illumination.
2. Vertical illumination.
3. Maintenance.
4. Shadows.
5. Direct glare.
6. Reflected glare.

In the chart, A+ denotes the highest degree of excellence, while D, the lowest, indicates that an installation of units so rated in this particular would very likely prove unsatisfactory where this factor is of prime importance.

3. *Location of Unit.*

Table III. shows the desirable spacing of units, according to the permissible mounting height. When these spacings are used, reasonably uniform illumination will result. Consult also the diagrams at bottom of Tables III. (*a*) and III. (*b*).

4. *Size of Lamp.*

After the position of the units has been settled on the plan according to the space permissible the size of the lamp can be determined by the consideration of the following factors :—

1. *The Room Index.*—In a large room with many points the system would have a higher coefficient of utilisation than in a small room. This is due to the fact that a number of units help to contribute directly the amount of light that reaches the table or bench without loss due to reflection from the walls, etc. The room index should be obtained from p. 2469, taking into consideration the proposed mounting height of a fitting.

2. *Depreciation Factor.*—Due to the settlement of dust and dirt on fittings and the deterioration in reflectivity of the walls and ceiling, the illumination will depreciate in the course of time. It is usual to allow a factor of 1·3 for reasonably clean locations and 1·5 where cleaning is infrequent or in dirty locations.

3. *Coefficient of Utilisation.*—On pp. 2537–2540 coefficiencies of utilisation are given for a particular fitting. Having chosen the fitting and obtained the value of the room index from Table IV., p. 2536, the corresponding coefficient of utilisation, according to the nature of the

eiling and walls can be readily obtained. This figure represents the percentage of the lumen enerated by the lamp that reach the plane of work.

$$\text{Lamp Lumens required per sq. ft.} = \frac{\text{Foot-candles} \times \text{depreciation factor}}{\text{Coefficient of utilisation.}};$$

$$\text{Area in sq. ft. per unit} = \frac{\text{Total floor area in sq. ft.}}{\text{Number of units.}};$$

$$\text{Lamp Lumens required per unit} = (\text{Area in sq. ft. per unit}) \times (\text{Lamp lumens required per sq. ft.}).$$

Having thus determined the lamp lumens required per point, the wattage of the lamp to be used an be obtained by reference to the following table.

LUMEN VALUES OF VACUUM AND GASFILLED ELECTRIC LAMPS.

Vacuum Type Lamps.			Gasfilled Lamps.		
Voltage.	Wattage.	Lumen Value.	Voltage.	Wattage.	Lumen Value.
50 to 80	20	158·5	25	15	168

	30	251·65	50/65	100	1,300
	40	336·87	50/65	150	2,100
	60	527·56	50/65	200	2,800
			50/65	300	4,600
200 to 250	20	145·18	50/65	500	8,500
	30	225·5			
	40	324·44	100/130	40	400
	60	510·84	100/130	60	750
			100/130	100	1,300
			100/130	150	2,100
			100/130	200	2,800
			100/130	300	4,600
			100/130	500	8,500
			100/130	1,000	18,000
			100/130	1,500	28,000
			200/520	60	550
			200/250	100	1,200
			200/250	150	1,800
			200/250	200	2,500
			200/250	300	4,200
			200/250	500	7,300
			200/250	1,000	16,500
			200/250	1,500	26,000

STANDARD TYPES OF GASFILLED LAMPS.

Type.	Sizes.
Opal or white sprayed	Standard sizes up to 500 watts
Bowl sprayed	Standard sizes up to 500 watts
Coloured sprayed Colours :—Red, Blue, Green, Amber, Yellow, Flame and Ivory.	Standard sizes up to 200 watts
Daylight	Standard sizes up to 500 watts

When the lamp lumens required, fall midway between two sizes, then it is usual to choose the larger rather than the smaller, unless it is certain that the less illumination from a smaller lamp will suffice.

Illumination Design for a Departmental Store Main Floor.

The following is an example in the procedure of designing illumination for a departmental main store:—

Store is 170 ft. long and 136 ft. wide with a 16 ft. ceiling. Columns divide the area into 17 ft. × 17 ft. bays. Ceiling, walls, and pillars are painted white. Supply voltage 200. Height of counter 3 ft.

Summary of Steps in the Design.	Reference.	Required Data
1. Foot-candles recommended	Table I.	10
2. Type of fitting used	Table II.—p. 2465	Unit No. 16
3. Spacing and mounting height		
Possible mounting height above work	Depends upon ceiling height	12 ft.
Maximum spacing permissible	Table III.(*a*)—p. 2467	18 ft.
Actual spacing to suit interior	Symmetrical lay-out with respect to bays	17 ft.
Actual mounting height above work	Ceiling type unit used	11½ ft.
Height above floor	—	14½ ft.
4. Size of Lamp		
Room index	Table IV.—p. 2469	5
Coefficient of utilisation	Table V.—p. 2470	0·55
Depreciation Factor	According to dust and dirt conditions	1·3
Lamp lumens required per point	Formula—p. 2462	6820
Lamp size	Table—p. 2462	500-watt gasfilled

INDUSTRIAL INTERIORS.

Works interiors:	
Offices—	
Private, general	10
Drawing office	15
Dressing rooms	4
Aisles, stairways, passageways, and corridors	3
Assembling shops—	
Rough work	5
Medium work	8
Fine work	10
Extra fine work	10–50
Store and stock rooms—	
Rough	3
Medium	6
Toilet and wash rooms	4
Cloth products:	
Light goods	10
Dark goods	20
Cutting, inspecting, sewing, pressing, cloth treating (oilcloth, etc.)—	
Light goods	8
Dark goods	12
Foundries—	
Charging floor, tumbling, cleaning, pouring * and shaking out *	5
Rough moulding and core making	6
Fine moulding and core making	10
Leather working:	
Pressing and winding—	
Light	8
Dark	10
Grading, matching, cutting, scarfing, sewing—	
Light	10
Dark	10–50
Textile mills:	
Weaving—	
Light goods	8
Dark goods	12
Knitting machines	10
Wood working—	
Rough sawing and bench work	5
Fine and bench and machine working, fine sanding and finishing	8

* Since 'pouring' and 'shaking out' are carried on in the same location as either 'rough' or 'fine' moulding, different illumination levels may be secured for these operations by cutting out some of the lighting circuits when space is used for the former.

TABLE II.—GUIDE TO THE SELECTION OF REFLECTOR EQUIPMENT.

	LIGHTING UNIT		EFFICIENCY BASED UPON ILLUMINATION ON HORIZONTAL	EFFICIENCY BASED UPON ILLUMINATION ON VERTICAL	FAVOURABLE APPEARANCE OF LIGHTED ROOM	DIRECT GLARE	REFLECTED GLARE	SHADOWS	MAINTENANCE

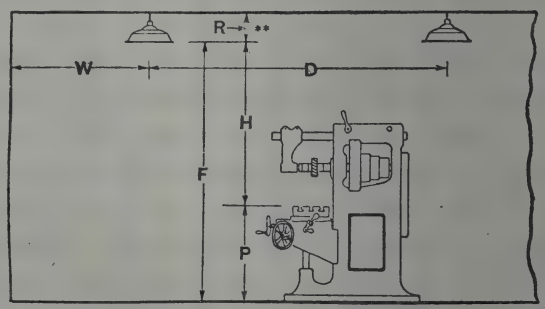
28	ENAMELLED METAL INDIRECT		C	C	B+	A+	A	A+	C

* For luminous bowl type, Rate A.

TABLE III. (*a*).—SPACING—MOUNTING HEIGHT.

Direct Lighting Units, including Semi-Enclosing and Totally Enclosing Units, No. 1 to No. 21.

Mounting Height of Unit.			Distance between Points and Sidewalls.	
Above Plane of Work. (H)	Above Floor.* (F)	Distance between Points. (D)	In Usual Locations where Aisles & Storage are Next to Wall. (W)	In Offices or where Work Benches are Next to Wall. (W)
4	6½	6	3	2
5	7½	7½	3½	2½
6	8½	9	4½	3
7	9½	10½	5	3½
8	10½	12	6	4
9	11½	13½	6½	4½
10	12½	15	7½	5
11	13½	16½	8	5½
12	14½	18	9	6
13	15½	19½	9½	6½
14	16½	21	10½	7
15	17½	22½	11	7½
16	18½	24	12	8
18	20½	27	13½	9
20	22½	30	15	10
22	24½	33	16½	11
24	26½	36	18	12
27	29½	40½	20	13½
30	32½	45	22½	15
35	37½	52½	26	17½
40	42½	60	30	20



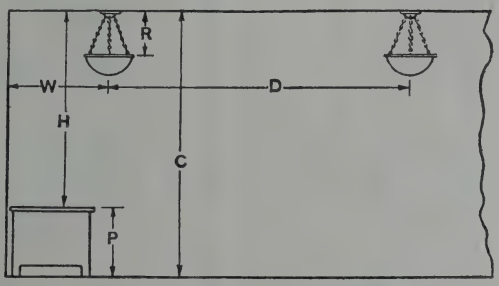
* Plane of work (P) assumed to be 2½ ft. above floor. When the plane of work is higher o lower than 2½ ft. above floor, neglect column (F) and work from column (H).

** Minimum allowance for (R) usually 1 ft.

TABLE III. (b) SPACING—MOUNTING HEIGHT.

Semi and Totally Indirect Lighting Units, No. 22 to No. 28.

Ceiling Height.		Spacing Distance Between Points.	Distance Between Points and Sidewalls.		Suspension Distance Ceiling to Top of Reflector.†
			In Usual Locations where Aisles and Storage are Next to Wall	In Offices or where Work Benches are Next to Wall	
Above Plane of Work. (H)	Above Floor.* (C)	(D)	(W)	(W)	(R)
5	7½	7½	3½	2½	1¼
6	8½	9	4½	3	1½
7	9½	10½	5	3½	1¾
8	10½	12	6	4	2
9	11½	13½	6½	4½	2¼
10	12½	15	7½	5	2½
11	13½	16½	8	5½	2¾
12	14½	18	9	6	3
13	15½	19½	9½	6½	3¼
14	16½	21	10½	7	3½
15	17½	22½	11	7½	3¾
16	18½	24	12	8	4
18	20½	27	13½	9	4½
21	23½	31½	15½	10½	5½
24	26½	36	18	12	6
27	29½	40½	20	13½	6¾
30	32½	45	22½	15	7½
35	37½	52½	26	17½	8¾
40	42½	60	30	20	10



* Plane of work (P) assumed to be 2½ feet above floor. When the plane of work is higher or lower than 2½ feet above floor, neglect column (C) and work from column (H).

† Suspension distances (R) in Table are based on best distribution of light and efficiency of utilisation for standard units. In some installations other considerations may require a different suspension distance.

Table IV.—Room Index.

Classify the room according to the proportions and the mounting height above the plane of work. Use upper column headings for direct-lighting units; for semi-indirect and totally indirect units choose column at bottom of page. Wherever the circumstances are such that the room index falls between two given figures, interpolate or use the smaller number.

Room Width.	Room Length.	Direct Lighting Units—Height Above Plane of Work. Feet												
Feet.	Feet.	4	5	6	7	8	9	10	12	14	16	20	24	30	40

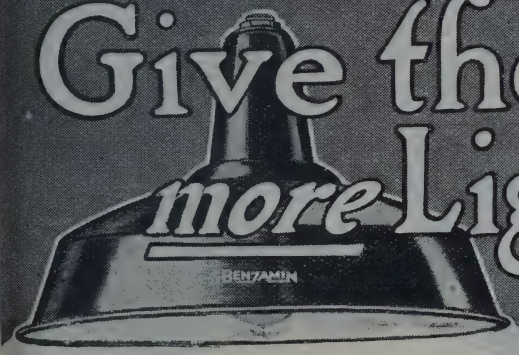
Give them more Light



AT the best, artificial light, as the majority know it to-day, is a poor substitute for the real article—but that does not necessarily mean that it cannot be improved.

Take Industrial Lighting, for instance. How many factories attempt to get anywhere near daylight intensity in the dark hours? The majority are satisfied so long as ***some*** light is provided of sufficient brilliancy to ***appear*** adequate.

The peculiar quality of daylight is due to its perfect diffusion, and it is this diffusion combined with high intensity which should be the aim of all users of artificial light.

The attainment of this ideal is not only possible but extremely simple—merely the use of suitable lamps in reflectors designed to give adequate and complete diffusion, and providing correct reflectors are used, it is practically impossible to have too ***much*** light.

Actual experience has proved that the increase in productive effort is greatly in excess, proportionately to the extra cost of increased lighting intensity.

GIVE THEM MORE LIGHT.

A Place for everything

— and everything in its place.

THE sound logic of our forefathers who perpetrated the above truism is no less applicable to-day than in their time. Thus, the attainment of increased production through Correct Industrial Lighting lies in the proper selection and installation of correctly designed equipment—reflectors specifically designed to meet individual conditions.

There are only two ways of doing things—the right and the wrong. By specifying and installing Benjamin Industrial Lighting Equipment and following the recommendations of Benjamin Engineers, correct equipment and installation are assured.

There is a Benjamin Reflector for *every* class of installation—in this case the Elliptical Angle Reflector was the only possible solution of the particular lighting problem—in other words, the right thing in its proper place.

Send for Catalogue No. 1000 to-day.

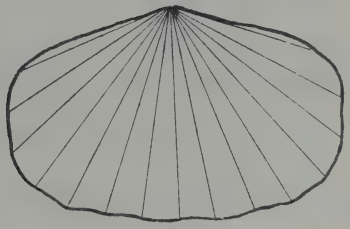

FIG. 10.

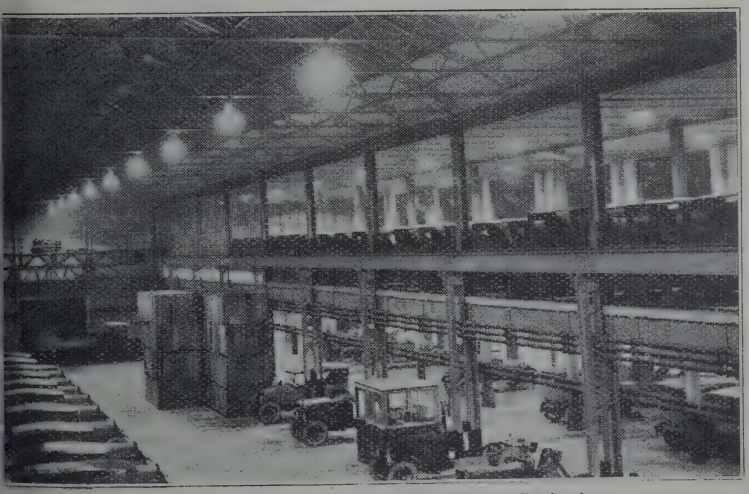

FIG. 11.—General Lighting in a large Motor Works (Benjamin R.L.M. Dispersive Reflectors).

It should be borne in mind that polar distribution curves represent the intensities correspond ing with different angles to the vertical or horizontal axis of an illuminant. The area enclose by such curves must not be associated with the total quantity of light emitted by the source.

Fig. 11 shows the excellent effect of using Benjamin R.L.M. Dispersive Reflectors in a large worl

Gas Lighting in Factories.

This may be either of high pressure (60 to 100 inches water gauge) or low pressure (4 6 inches water gauge).

The amount of gas that must be consumed to provide a given number of foot-candles illumination over the area of a workshop may be computed as follows:—

High pressure $\frac{A \times I}{200}$ = c. ft. per hour; Low pressure $\frac{A \times I}{100}$ = c. ft. per hour,

where A is the area to be lighted in square feet and I is the average illumination required foot-candles.

Thus assume a workshop having a floor area of (say) 2,000 sq. ft., and an avera illumination of 4 ft.-candles is required. According to the foregoing formula, the lighting uni as a whole would have to consume,

High pressure $\frac{2{,}000 \times 4}{200}$ = 40 c. ft. per hr. Low pressure $\frac{2{,}000 \times 4}{100}$ = 80 c. ft. per hr.

Generally it will not pay to put in high-pressure plant unless the total candle-power exceed 1,000 candles.

It remains to subdivide the installation into separate lighting units, so as to ensu as nearly as possible a uniform illumination in order that all parts of the workshop are equal available for practical use.

For instance, to develop the light from 80 cubic feet of low-pressure gas, any one of th following arrangements may be used.

No. of Lamps. . .	20	16	10	8
Cub. ft. per hour, each	4	5	8	10
Total of all Lamps .	80	80	80	80

Even larger lamps may be used, units ranging from 25 to 4,000 candle-power being avai able. The particular arrangement that may be used will depend partly upon the structur features of the building and the kind of work being done. Sometimes a uniform illuminatio must be aimed for, or in other cases it may be desirable to have certain areas extra-illuminate the intervening areas being somewhat subdued.

Generally it is not advisable to rely upon the reflecting power of walls, because in the fir place the use of reflecting shades prevents much of the light from the lamps reaching the wall and secondly, although the whitewashed surfaces have a reflection coefficient of 80 per cen when new, this rapidly deteriorates to less than half this value, due to dust created by movin machinery.

The greater the candle-power of the lighting unit used, the higher it should be placed; an in order that the illumination from the separate lamps shall overlap they should be dispose so that the distance between their centres is 1½ to 2 times their height above the level at whic work is being done.

The following points may be noted:—

If gas lamps have to be arranged amongst running shafting or belting, remote control ma be used to ensure safety in lighting and extinguishing.

If there is excessive vibration the premature fracture of mantles can be prevented by usin anti-vibrators.

Gas lamps may be arranged if required for use at various heights.

If the air round the lamps is extraordinarily dusty, the use of Keith-Blackman's 'group system will ensure their perfect working.

For large work, lamps 9 feet to 10 feet above floor level will be found convenient This ould need moderate size lamps, consuming 10 to 15 cubic feet per hour and spaced 9 to 12 feet tween centres.

For smaller work, lamps consuming 5 cubic feet per hour, set at 7 to 8 feet above floor level id 6 to 9 feet between centres, will be found suitable.

Artificial Daylight.

On many occasions it is essential that artificial lighting shall approximate in quality to that btained during the daytime. Particularly is this important in artists' studios and picture alleries, since the light obtained from an incandescent lamp has a greater proportion of red diation than daylight. This has the effect of the blue and violet colours losing their life and ie yellow and red becoming accentuated. Again in dye works and in some shops it is necessary match colours, and in order to facilitate operation under such circumstances after daylight veral expedients have been devised.

A gas-filled lamp is now available in which the filament operates in a selectively tinted blue aylight bulb, which has the effect of filtering the causes of red radiation. It is essential, however, bear in mind that when daylight lamps of this order are being used that a lamp of sufficient attage be employed. It is a good rule to bear in mind that, if under ordinary circumstances a 0-watt lamp is required, then in order to produce approximately daylight effects a 100-watt aylight lamp will be required.

A further use for these gas-filled lamps is their employment in the grading of flour or the rading of leather. It sometimes happens that even the colour which is obtained in this way s not sufficiently accurate, in which case special glass filters and reflecting materials have been esigned. In such few cases in which they must be employed it is still more important to have n ample size of electric lamp. (See 'Standard Types of Gas-filled Lamps,' p. 2529.)

SECTION XXXVIII

PART IV

FIRE EXTINCTION.

STANDARDS OF FIRE-RESISTANCE.

STANDARD TABLE FOR FIRE-RESISTING SINGLE DOORS, WITH OR WITHOUT FRAMES.

Classification.	Sub-Class.	Duration of Test at Least.	Minimum Temperature.	Thickness of Material.	Minimum Superficial Area under Test.	Minimum Time for Application of Water under Pressure.
		Min.	Deg. F.		Sq. Ft.	Min.
Temporary protective class	A	45	1500	2 in. and under	20	2
	B	60	1500	Optional	20	2
Partial protective class	A	90	1800	2½ in. and under	20	2
	B	120	1800	Optional	20	2
Full protective class	A	150	1800	½ in. and under	25	2
	B	240	1800	Optional	25	5

(*International Fire-prevention Congress.*)

Fire-Resisting Substances.

Exhaustive tests seem to show that sulphate of aluminium is one of the best fire-resisting ıbstances for wood, as it checks combustion by forming an infusible and non-conducting coat-ıg, while such substances as ammonium sulphate or ammonium phosphate when heated check ɔmbustion by emitting an incombustible gas.

The following is the formula for what is known as the United States 'Government white-ash mixture,' which also acts as a fire-retarding coating over interior wooden surfaces:—lake a half bushel of quicklime with boiling water, keeping it covered during process; strain ɔd add one peck of salt dissolved in warm water; put 3 lbs. ground rice in water and boil to a lin paste; ½ lb. of powdered Spanish whiting; 1 lb. of clean glue dissolved in hot water. Mix ell and let it stand for several days. Keep the mixture in a kettle or receptacle, and apply as ɔt as possible with a whitewash or paint brush.

(See also p. 435.)

Fire Streams.

TABLE SHOWING PRESSURE REQUIRED AT NOZZLE AND AT PUMP, WITH QUANTITY AND PRESSURE NECESSARY TO THROW GOOD EFFECTIVE STREAMS VARIOUS DISTANCES THROUGH DIFFERENT SIZE NOZZLES, USING 100 FEET OF ORDINARY 2½-INCH RUBBER-LINED HOSE AND SMOOTH NOZZLES.

N.B.—The above pressures are based on the supposition that the hose is coupled direct to the delivery of the pump and while the stream is flowing; if, however, the hose is coupled to a hydrant which is supplied direct from the pump, then the corresponding fire pump pressure must be greater than the hydrant pressure by an amount equal to friction loss and difference of head between hydrant and pump.

The pressures given in the table are *indicated* pressures, not effective pressures; effective pressures would be slightly greater.

The distances given are for *effective* fire *streams* adapted for fire purposes, and are not for mere isolated drops. (*Freeman.*)

Fire Streams and Electric Circuits.

It has always been believed to be dangerous to those handling a hose line to allow the stream come in contact with an electric circuit. Prof. F. C. Caldwell has found by experiment that ere is no danger of shocks when the distance between the nozzle and circuit is more than ft., irrespective of the voltage. (*'Power.'*)

Fire Extinguishers.

Sawdust possesses some special merits as a fire extinguisher when dealing with small outeaks of liquid combustibles, such as lacquer and petrol, which are usually difficult to extinguish ordinary means. Sand is generally looked upon as the best substance to use in such cases hen it can be applied promptly, but tests have shown sawdust to be superior.

The British Fire-Prevention Committee carried out a series of tests, the results of which nded to prove that sawdust intimately mixed with bicarbonate of soda and applied in ilk has certain advantages over sand and similar materials as an extinguishing medium for comaratively small fires occasioned by the ignition of the vapour of petroleum spirit (petrol) and her inflammable liquids. Ordinary sawdust, as obtained from saw-mills, is the most suitable r this purpose. It must be free from shavings and chips of wood, but it does not require to be ther specially dried or to contain added moisture. The addition of bicarbonate of soda, although ot essential, is advantageous. The Committee found an effective proportion of bicarbonate of oda to sawdust to be 10 lbs. to 1 bushel (or, say, 12 lbs.) of sawdust. The Committee wished to mphasise the fact that so far their investigations had been limited to small quantities of inammable liquids, not exceeding 2 gallons, and the areas over which they were spread did not xceed 6 ft. square. These conditions are met with in motor garages and hangars, for which, the opinion of the Committee, the proposed mixture is applicable and economical. The Committee added that their tests showed that the application of this or any similar mixture in small uantities from tubes or canisters does not give satisfactory results.

Some extensive tests carried out by the Standard Oil Company have proved that the foam ethod of fighting oil fires is ineffective unless the foam is applied gently at the surface of the urning oil. A 55,000-barrel tank burned right out although enough foam was dropped into it o form a blanket 6 ft. thick. When, however, the foam was applied through asbestos pipes eaching to the surface, experimental fires in the same tank were quickly put out.

British Standard Specification for Materials and Constructional Strength of Chemical Fire Extinguishers.*

(*Abstract.*) (No. 138—1922.)

Definition.

1. The term 'Chemical Fire Extinguisher' under this Specification denotes a vessel or achine manufactured as a Fire Appliance in which the pressure necessary to project the xtinguishing fluid is generated automatically either by chemical action or by the release of ompressed gas in a capsule within or affixed to the vessel itself.

Size.

2. This Specification applies only to Extinguishers having a fluid capacity of three Imperial allons and under.

Shape.

3. The shape of the vessel may be cylindrical or conical.

Method of Actuating.

4. The machine may be actuated in any of the following ways :—

(*a*) By breaking a hermetically sealed bottle containing acid and thereby allowing this acid to come into contact with an alkaline solution.

(*b*) By turning over the vessel and thereby spilling acid from a bottle into the alkaline solution.

(*c*) By opening a sealed capsule containing high-pressure gas within or affixed to the vessel.

These operations may be performed by striking a knob on the top of the machine, by a blow n the side, or by other means.

* By permission of the British Engineering Standards Association.

Material and Construction.

5. The vessel may be made either of sheet steel or copper, and the body may be jointed solid drawn.

If jointed, riveted or locked joints may be used for conical bodies, and riveted joints on for cylindrical bodies.

The ends may be attached to the bodies by riveted or lapped and edged-over joints.

All joints shall be thoroughly soldered, and longitudinal joints which are not riveted shall protected internally by means of a soldered strip or similar fitting.

Dimensions and Thickness.

6. Cylindrical jointed or solid-drawn bodies and ends after dishing shall be made in not le than the following thicknesses :—

Diameter.	Minimum Thickness.	
	Steel.	Copper.
Up to and including 4 ins. (101·6 mm.)	18 S.W.G. (1·22 mm.)	18 S.W.G. (1·22 mm.
Above 4 ins. (101·6 mm.) and up to 6 ins. (152·4 mm.)	18 ,, (1·22 mm.)	16 ,, (1·63 mm.
Above 6 ins. (152·4 mm.) and up to 7 ins. (177·8 mm.)	18 ,, (1·22 mm.)	14 ,, (2·03 mm.
Above 7 ins. (177·8 mm.) and not exceeding 8 ins. (203·2 mm.)	16 ,, (1·63 mm.)	14 ,, (2·03 mm.

Conical bodies shall be of the following thicknesses :—

Diameter at large end.	Minimum Thickness.	
	Steel.	Copper.
Up to and including 9 ins. (228·6 mm.)	18 S.W.G. (1·22 mm.)	16 S.W.G. (1·63 mm.)

The ends for both cylindrical and conical bodies shall be dished outwards to a radius no exceeding the diameter of the body at the point of attachment.

Cap and Opening.

7. The cap shall be of brass or gunmetal of ample strength.

Cap Joint.

8. The cap joint shall be made of good quality leather well greased or of acid-resisting rubbe or other approved material, and shall not exceed $\frac{1}{8}$-inch (3·18 mm.) in thickness.

Plunger.

9. The plunger or striker shall be made of brass or gunmetal. The diameter of the plunge shall be not less than 0·2 times the stroke, with a minimum of $\frac{1}{4}$-inch (6·35 mm.) diameter.

Test Pressure.

12. Every Chemical Fire Extinguisher purporting to be made in accordance with this Spec fication shall, when completed, be tested with cap screwed on and shall withstand an interna hydraulic test pressure of 300 lbs. per sq. in. (21·09 kgs. per cm.²), which shall be maintaine for at least five minutes without leakage or distortion.

Testing Connection.

13. A test connection screwed externally with a British Standard Pipe Thread shall be fitte on each machine either on the nozzle or other suitable position.

Discharge Fittings.

14. Suitable strainers shall be fitted to all discharge openings or tubes.

Expansion Outlet.

15. Suitable means shall be provided to prevent the fluid being discharged from the nozzl in the event of normal rise in temperature of the room in which the extinguisher is situated.

Interior Coating.

16. The extinguisher shall be well tinned or lead coated internally.

Clearance.

17. The clearance or air volume above the fluid level mark shall be such that the pressure the machine does not exceed 100 pounds per sq. in. (7·03 kgs. per cm.²) when discharged with ›en nozzle and with the temperature of the fluid up to 100° F. (37·7° C.).

Nozzle.

18. The nozzle shall be of brass or other corrosion-resisting metal and of stout construction. o taps shall be used.

Fire-Resisting Buildings.

The following is a reasonable standard for these :—

Walls should be of hard burnt brick or cement concrete (composed of cement and an aggregate sand, gravel, broken brick, burnt ballast, furnace slag, clinker or the like—a coke breeze aggre-.te should be avoided). The thickness of walls depends upon the duties they have to perform, it external or party walls should be at least 9 ins. thick at every point, and the latter should be rried well above the adjoining roofs and should be thicker than the external walls.

Walls built as described above and containing no openings are of great value in checking the ›read of a fire.

It should be noted that stone walls are undesirable features as they crumble on the combined ›plication of heat and water.

Roofs should be constructed as strongly as possible of incombustible material, and if glass is ›cessary, wire glazing should be used. Broken panes should be replaced immediately.

Floors require to be of incombustible material, such as concrete or ferro-concrete, but it is .ite safe to lay a wood floor flush on the concrete, *i.e.* leaving no intervening space.

All structural metal work in a floor, as also any columns or stanchions supporting the floor, ould be encased in plaster cement or concrete, as otherwise their strength is rapidly reduced on .e application of heat. Further, the piercing of floors with lifts, hoists, staircases, etc., detracts ›eatly from their value, and such lifts, etc., should be totally enclosed in brick or concrete with ›e-resisting doors to each opening into the various floors.

Windows should have wire glazing in steel frames, and partitions should be of concrete slabs hard wood. Matchlining should be avoided.

Any communications with adjoining buildings should be protected by double fire-resisting ›ors or fire-resisting compartments, especially if such adjoining buildings are of a lower standard construction.

Dubbing for Preserving Leather Hose.

Melt 2½ lbs. of perfectly clean tallow, free from salt, and mix with it when hot 1 gallon or lbs. of cod oil.

The best mode of clearing tallow for this purpose is to boil it in water, which will take up the .lt and other impurities, and can be poured away when cold.

Care must be taken not to boil the oil, as this would deprive it of some of its principal ›alities.

The tallow must be first melted, and when it is warm the oil is to be poured on, and stirred ›to it until the whole mixture is perfectly cold. This will make a good stiff dubbing.

Legal.

Definitions of Minerals and Mines.

By the term 'mineral,' as used in legal documents, is meant a constituent of the earth's crust ıich possesses in its severed condition an intrinsic value by virtue of its composition, that is to y, 'any substance that can be got from within the surface of the earth which possesses a value use apart from its mere possession of bulk and weight' (Lord Fletcher Moulton, Court of ıpeal, Nov. 23, 1908). The meaning of the word 'mineral' may be affected by the context; cording to Lord Halsbury, in 'a grant of *mines* and *minerals*,' it 'is a question of fact what ese words meant in the vernacular of the mining world, the commercial world and landowners the time when they were used in the instrument' (Lord Provost of Glasgow *v.* Fairie, 13 App. ıs, 1888).

In this country a *mine* is defined as a working for mineral carried on by artificial light without :entionally disturbing the surface, whilst a *quarry* is an excavation for the extraction of mineral en to the day; the distinction is important from a legal point of view. It must be noted that quarry less than 20 feet deep is by law classed as a factory. In many other countries, notably the United States of America, the distinction between a 'mine' and a 'quarry' depends not ıon the method of working but upon the mineral wrought, any working for e.g. building stone, ıether underground or open, being classed as a quarry. In legal instruments 'mine' sometimes .s the wider meaning of the space containing the minerals, or even from which the minerals .ve been extracted.

Ownership of Minerals.

In this country the mineral occurring within any area is the property of the owner of the :ehold of the surface, with some few exceptions, the most notable of which are the Forest of ean and the Isle of Man, where the minerals are Crown property. Minerals containing precious etals—where these metals form the essential value of the mineral—are the property of the :own wherever found (except in Scotland). Minerals under copyhold land were mostly the pro- :rty of the Lord of the Manor, who could not, however, as a rule, deal with them save with the ınsent of the copyholder. Since by the Law of Property Act, 1922 (12 & 13 Geo. V. ch 16, s. 128), ›pyhold has been abolished, the minerals are as a rule enfranchised and become the property the tenant, although the latter may, if he so desire, transfer his right to the lord. This law .me into force on January 1, 1926 (Law of Property Act (Postponement) Act, 1924).

Generally speaking, in this country the minerals are leased to those exploiting them. 'A ining lease is really a sale payable by instalments' (Henn Collins, Master of the Rolls, *In re* ldam's Settled Estates, Chanc. 2, 1902). Most often the rental is based on the tonnage exploited, ıe rate per ton or *royalty* being fixed. For coal this may range from 2*d.* to 2*s.*, but is usually :tween 4*d.* and 7*d.*, the average for the United Kingdom having been pre-war probably just

about 5½*d.* per ton (Royalties Commission, 1889); it is now (1928) 5·74*d.* including wayleav per ton of saleable coal raised. Sometimes the rental is a fraction of the value of the coal, th ranging from ⅛ to $\frac{1}{50}$; sometimes the rental is a proportion of the profit made; sometimes a pri per inch thickness of coal seam per acre wrought out forms the rental. In addition to royalt wayleaves have often to be paid for; average wayleave in United Kingdom is about ¼*d.* per t (Royalties Commission, 1889).

Royalties on stratified ironstone vary from 2½*d.* to 1*s.* 6*d.* per ton, averaging about 6*d.*

In the hæmatite mines of Cumberland and Lancashire the royalties vary normally fro 1*s.* to 2*s.*, averaging about 1*s.* 4*d.* In the Forest of Dean royalties on iron ore vary from 3*d.* 5*d.* per ton.

Royalties in Cornwall on tin and copper ores range from $\frac{1}{30}$ to $\frac{1}{10}$ of the value of the mineral raise

Royalties on lead and zinc ores range from ⅛ to $\frac{1}{30}$ of the value of the ore raised.

Royalties are often on a sliding scale, the ratio increasing with the market price of the miner or of its metallic contents.

Land Tax Redemption Act, 1798, and subsequent Acts; 'The Mining Code,' Railway Claus Consolidation Act, 1845, Ss. 74–85; Waterworks Clauses Consolidation Act, 1847, Ss. 18–2 Public Health (Support of Sewers) Act, 1883—see, however, New Moss Colliery *v.* Manchest Corporation, 1908, and Howley Park Coal and Canal Co. *v.* L. & N.W. Railway, 1912; Copyho Act, S. 48, 1852; Coal Mines Act, 1866; Metalliferous Mines Acts, 1872, 1875; Explosives A 1875; Rating Act, 1874; Stratified Ironstone Mines (Gunpowder) Act, 1881; Conveyanci Act, S. 2, 1881; Slate Mines (Gunpowder) Act, 1882; Coal Mines Regulation Act, 1887; Quarri (Fencing) Act, 1887; Quarries Act, 1894; Coal Mines (Check Weigher) Act, 1894; Workmer Compensation Act, 1897; Coal Mines (Weighing of Minerals) Act, 1905; Workmen's Compens tion Act, 1906; Notice of Accidents Act, 1906; Coal Mines Regulation (Eight Hours) Act, 190 Small Holdings and Allotments Acts, Schedule I., 1908; Mine Accidents (Rescue and Aid) A 1910; Coal Mines Act, 1911; Coal Mines (Minimum Wage) Act, 1912; Coal Mines Act, 191 Feudal Casualties (Scotland) Act, S. 7, 1914; Price of Coal (Limitation) Act, 1915; Coal Min Control Agreement (Confirmation) Act, 1917; Coal Mines Regulation (Amendment) Act, 191 Petroleum (Production) Act, 1918; Coal Mines Act, 1919; Coal Industry Commission Act, 191 Coal Mines (Emergency) Act, 1920; Mining Industry Act, 1920; Finance (1909–10) Act, 191 Ss. 1–5, 20–24, 25–27, 33, 34; Finance Act, 1912, S. 11; Finance (No. 2) Act, 1915, S. 43; Finan Act, 1916, S. 46; Finance Act, 1917, S. 21; Income Tax Act, 1918, Schedule III.; Finance A 1919, S. 33; Finance Act, 1920, Ss. 49, 7; Mines (Working Facilities and Support) Act, 192 See Report of Mining Cases decided by the Railway and Canal Commission Court under the Min (Working Facilities and Support) Act, 1923, by P. G. Bamber. Coal Mines Act, 1926 (Amen ment of 1908 Eight Hours' Act for 5 years).

Principal Clauses in Colliery Lease.

Description of contracting parties (lessor and lessee) and of property demised.

Powers granted to lessee:—
- To break surface, make shafts, adits, etc.
- To win and work coal, bring to bank, make merchantable, dispose of.
- To work by instroke or outstroke or both.
- To make and dispose of coke and other products.
- To have necessary surface accommodation.
- To have necessary wayleaves.
- To construct roads, tramways, railways, etc.
- To erect buildings, machinery, plant, etc.
- To work quarries of lime, clay, etc. (sometimes for own use only).
- To remove coals, dead and live stock, plant, etc., after expiration of lease.
- To relinquish at stated times before termination of lease.
- To renew lease for a further period.
- To generally do all things necessary for getting coal, etc.

Reservations to lessor:—
- Of mines and minerals not demised.
- Of certain rights and wayleaves.
- Of use of ways, railways, etc.

'Habendum':—
- Lessee to have and hold property for a fixed term of years.

'Redendum':—
- Annual certain rent or deadrent, usually merging into royalty.
- Royalty per ton or otherwise.
- Rent for surface occupied.
- Rent for wayleaves, waterleaves, or other facilities.

Provisoes:—
- No royalty payable in respect of colliery consumption.
- Power to make up short workings of previous years.
- Power to carry over excess workings to subsequent years.
- For distress in case of default in payments.
- For re-entry if rents, etc., remain unpaid for certain period.

Covenants on part of lessee :—
For due payment of rents and royalties.
For due payment of taxes.
For compensating for damage done to surface or to neighbours.
For erecting (or against erecting) buildings, houses, coke-ovens, etc.
For keeping proper accounts accessible to lessor, and rendering the same.
For keeping proper mine plans, and permitting inspection of mine.
For leaving proper barriers.
For working in approved and miner-like manner.
Against sub-letting without authority.
For giving up possession in good condition at determination of lease.
For keeping mine, plant, buildings, etc., in good repair.
For properly fencing or securing shafts, adit mouths, etc.
For giving lessor power to purchase plant, etc., at a valuation on determination of lease.
Covenants on part of lessor :—
For proper title.
For quiet enjoyment.
Arbitration clause.

Leases of ironstone mines as also of metalliferous mines follow practically the same lines; regards the latter, it is usually set forth that the royalty shall be a certain part of the value the minerals, cleaned, dressed, smelted, or otherwise rendered merchantable, as the case may mand, at the expense of the lessee. There are often clauses specifying that a certain amount development work, driving, sinking, etc., shall be performed.

A tacknote or license to prospect is often granted; this differs from a lease, inasmuch as it ansfers no interest in the property. Its usual form is a license for one year to explore for all for certain specified minerals within a definite area, usually for a nominal consideration, the ensee making compensation for all damages, and paying a royalty on all minerals gotten and ld. The license is generally renewable at the option of the licensee for a term of years, usually ree, and the licensee is entitled to a lease upon conditions specified; this specification often kes the form of a schedule embodying the conditions of a draft lease.

Classification of Mineral Deposits.

A mineral deposit may be defined as a portion of the earth's crust containing mineral matter intrinsic value under favourable conditions.

The mineral substances that form the subject of mining operations may be classified as ıder :—

Group I., Fuels; II., Ores; III., Salts; IV., Gems: V., Rocks.

Group I. contains the different varieties of coal, asphalts, bitumen, and other solid hydrocarbons, mineral oils, etc., while sulphur may conveniently be included.

Group II. contains the various heavy metals either in the native state or in combination.

Group III. contains the haloids, sulphates, carbonates, silicates, phosphates, borates, etc., the alkaline earths and alkalies.

Group IV. contains those minerals that are prized as gems on account of their hardness, illiancy, and transparency, as well as the semi-gems, such as opal, turquoise, etc., which though aque are prized as precious stones on account of the beauty of their colouring and their rarity.

Group V. comprises the various rock masses, such as granite, slate, limestone, etc., the ploitation of which is more properly considered under quarrying.

With respect to their mode of occurrence, mineral deposits may be classified morphologically follows :—

- Tabular = Beds, veins.
- Irregular = Masses, lenses, pipes, etc.

A more complete classification, based on genetic as well as morphological characters, is as llows :—

Class I.—Symphytic; Syngenetic, contemporaneous or stratified
- Group *a*, clastic.
- „ *b*, formed by chemical agencies.
- „ *c*, formed by organic agencies.
- „ *d*, disseminated through beds.

Class II.—Epactic; Epigenetic, subsequent or non-stratified.
- Sub-Class A—Veins.
  - Group *a*, fissure.
  - „ *b*, bedded.
  - „ *c*, contact.
  - „ *d*, gash.
- Sub-Class B—Masses.
  - Group *a*, stockworks.
  - „ *b*, disseminated in igneous rocks.
  - „ *c*, connected with igneous rocks.
  - „ *d*, connected with soluble rocks.

Class I.—Group *a* includes auriferous alluvials, tin-bearing alluvials, ironsands, etc. Group *b* ntains deposits due to chemical precipitation, to evaporation or to metasomatic changes. ractically all the stratified ironstones belong to this group. Of group *c* the most important

representative is coal. Group *d* includes the Knottensandstein of Mechernich, the Kupfer schiefer of Mansfeld, the Banket beds of Johannesburg, and similar deposits.

Class II.—Sub-Class A. Group *a* includes most of the important vein systems of the world such as those of Cornwall, etc.

Group *b* includes veins parallel to the stratification.

Group *c* embraces certain veins following the contact of dissimilar rocks.

Group *d* contains veins carrying galena and zinc blende that characterise certain limestone districts, e.g., that of Missouri.

Sub-Class B. Group *a* consists of masses traversed by minute veinlets carrying ore, such as the tin deposits of Saxony.

Group *b* comprises such deposits as the Kimberley diamond-bearing pipes, the copper deposits of Lake Superior, etc.

Group *c* are very largely lenticular in form; the pyrite deposits of the Huelva district are a typical example.

Group *d* may be represented by the red hæmatite deposits of Cumberland and Lancashire.

Branches of Mining.

I. Prospecting, the most important part of which is 'boring.'

II. Exploiting, including the various operations of opening up mineral deposits by shafts or adits, extracting and transporting the mineral, securing, pumping and ventilating the workings and the proper care of the men employed.

III. Dressing or preparing the mineral extracted for the market.

COAL.

Classification.

Coal is generally classified under the three main heads of 'lignite' or 'brown coal,' 'bituminous coal,' and 'anthracite.' Bituminous coal is further classified according to the purposes for which it is best adapted, such terms as gas coals, house coals, furnace coals, smithy coals, steam coals, etc., being usually employed. The classification that is most widely adopted is based upon Gruner's work, and is as follows :—

Description of Coal.	Composition of Ash-free Coal.			Percentage of Fixed Residue.	Nature of Residue.	Calorific Power.
	Carbon.	Hydrogen.	Oxygen.			Cal.
Lignite	70–75	5·6	15·25	50	Non-coking	6,000
Dry coals with long flame (furnace coals)	75–80	4·5–5·5	15–19·5	55–66	Pulverulent or very slightly coking	8,000–8,500
Fat coals with long flame (gas coals)	80–85	5·0–5·8	10·0–14·2	60–68	Completely agglomerated, porous	8,500–8,800
Fat coals proper (smithy coals)	84–89	5·0–5·5	5·5–11·0	68–74	Completely agglomerated, more or less porous	8,800–9,300
Fat coals with short flame (coking coals)	89–91	4·5–5·5	5·5–6·5	74–82	Coked, compact	9,300–9,600
Anthracite	90–93	4·0–4·5	3·0–5·5	82–90	Pulverulent	9,200–9,500

Seyler's classification is based upon the percentage of hydrogen in the ash-free coal and the ratio of carbon to hydrogen :—

Genus.	H per cent.	C : H.
1. Anthracite	< 4	> 22
2. Carbonaceous	4–4·5	20·3–23·35
3. Semi-bituminous	4·5–5	16·6–20·4
4. Bituminous	5–5·8	14·6–18·2
5. Per-bituminous	> 5·8	12·9–14·7

(*Strahan & Pollard.*)

CLASSIFICATION OF THE INTERNATIONAL GEOLOGICAL CONGRESS, CANADA.

Class.	Name.	Fuel Ratio.	Composition.			Percentage of Volatile Combustible Matter.	Calorific Power B.Th.U.
			C.	H.	O & N.		
A_1	Anthracite	12 or more	93–95	2–4	3–5	3–5	14,500–15,000
A_2	Semi-Anthracite	7–12	90–93	4·4·5	3–5·5	7–12	15,000–15,500
B_1	High Carbon Bituminous	4–7	80–90	4·5–5	5·5–12	12–15	15,200–16,000
B_2	Bituminous	1·2–7	75·90	4·5–5·5	6–15	12–26	14,000–16,000
B_3	Low Carbon Bituminous	—	70–80	4·5–6	18–20	up to 35	12,000–14,000
C	Cannel	—	—	—	—	30–40	12,000–16,000
D_1	Lignitic	—	60–75	6–6·5	20–30	—	10,000–13,000
D_2	Lignite	—	45–65	6–6·8	30–45	—	7,000–11,000

Class B_2 comprises most of the coking coals; in Class D_1 moisture is 6–20 per cent., in D_2 over 0 per cent.

CLASSIFICATION OF THE IMPERIAL MINERAL RESOURCES BUREAU.

A, Brown coal or lignite; B_1, gas coal and cannel; B_2, coking coal: B_3, house coal; B_4 manufacturing or iron smelting coal; B_5, steam coal; C, anthracite.

Other classifications are also used; one much liked in America is based upon the 'fuel ratio,' that is, the figure obtained by dividing the percentage of fixed carbonaceous residue by the percentage of volatile matter.

CONSTITUTION OF COAL.

The four constituents of coal, as identified by Dr. Marie Stopes, are :—

(1) Fusain. (2) Durain. (3) Clarain. (4) Vitrain.

Vitrain appears to contain the lowest proportion of inherent ash, and it and clarain are practically the only coking constituents. These two also yield the largest proportions of gas, especially of hydrogen, on carbonisation.

CALORIFIC POWER.

The calorific power may be calculated from the ultimate analysis by the 'Deutscher Verband' formula :—

$$\text{Cal. power in calories} = 81\,C + 290\left(H - \frac{O+N}{8}\right) + 25\,S - 6\,W,$$

where C, H, O, N, S, and W are the percentages, respectively, of Carbon, Hydrogen, Oxygen, Nitrogen, Sulphur, and Moisture.

Gontal's formula is applied where only the proximate analysis (percentages of fixed carbon, volatile matter and ash) is known.

Let C be percentage of fixed carbon, V of volatile matter, A of ash; then

$$\text{Cal. power in calories} = 82\,C + a\,V,$$

where a is a coefficient depending upon the percentage of volatile matter in the ash-free coal, i.e. upon $\frac{100\,V}{100-A}$ as follows :—

$\frac{100\,V}{100-A}$	5	10	15	20	25	30	35	40
a	145	130	117	109	103	98	94	80

The ash of coals varies usually between 3 and 15 per cent.

1 lb. of ordinary coal requires theoretically 130 cub. ft. of air for complete combustion.

COKE.

Ordinary bituminous coal, containing 25 to 30 per cent. of volatile matter, coked in a modern regenerative bye-product coke-oven plant, yields approximately :—

Coke	70–75 per cent.
Tar	3·5–4·5 ,,
Ammonia as ammoniac sulphate	1–1.25 ,,
Crude benzol	1 ,,

Surplus gas, 3,000 to 5,000 cub. ft. per ton of coal.

The composition of this gas is about as follows:—Hydrogen, 48 to 55 per cent.; methane 25 to 34 per cent.; carbonic oxide, 6 to 8 per cent.; carbonic acid, 2 to 2·5 per cent.; hydrocarbons, 2 to 4 per cent.; nitrogen, etc., 5 to 12 per cent. The calorific power is about 480 to 600 B.Th.U. gross, or 425 to 550 B.Th.U. net.

Weight of Coal.

The specific gravity of coal varies from 1·1 to 1·6, most bituminous coals approximating to 1·3. The following table shows the weight of coal contained in one acre of superficial area per inch thickness of seam.

Table of the Weight of Coal under Different Circumstances.

Specific Gravity.	Weight in the Natural Bed, per Acre, per Inch Thick, in Tons.	Weight of a Cubic Foot in the Broken State, in Lbs.	
		Large Coal.	Small Coal.
1·10	111·411	42·62	37·12
1·15	116·475	44·56	38·81
1·20	121·540	46·50	40·50
1·25	126·604	48·43	42·18
1·30	131·668	50·37	43·87
1·35	136·732	52·31	45·56
1·40	141·796	54·25	47·25
1·45	146·860	56·18	48·93
1·50	151·925	58·12	50·62

Specific gravity × 101·283 = weight in tons per inch thick per acre.

To find the contents of coal of any given specific gravity per acre multiply the figure in the table by the thickness of the seam in inches; the thickness measured along a vertical line should always be taken, as the correct result will thus be obtained, whatever may be the inclination of the coal seam.

The weight of coal in its broken state, that is, as it comes to the surface, in tubs or otherwise, will depend on its largeness; the large has here, however, been computed to weigh in proportion to the solid coal as 62 to 100, and the small as 54 to 100.

The calculation now most commonly adopted in the North of England to ascertain the weight of coal in the solid state is to reckon 19 cwts. per cubic yard = 78·815 lbs. per cubic foot. On this calculation, a seam 1 foot in thickness would contain 1,532 tons 13 cwts. 1 qr. 10 lbs. per acre, and a seam 1 yard thick would contain 4,598 tons per acre.

A summary way of reckoning the quantity of available coal in a given area of a seam is to take an acre of coal 1 inch thick to produce 100 tons. This leaves a sufficient margin for faults and losses in barriers and in working.

Sizing of Coal.

In the coal trade coal is often sold by size, but there is no uniformity in practice even in the same field. Above 4 ins. to 6 ins. is usually sold as Best Coal, House, or Best House; a very general scheme of designations is:—

Cobbles	between 5 ins. to 6 ins.	and about	3½ ins. to 3 ins.
Treble nuts	3½ „ 3 „	„	1½ „
Double nuts	1½ ins.	„	1 in. to ¾ in.
Single nuts	1 in. to ¾ in.	„	⅝ in.
Duff, slack or gum below ⅝ in.			

Some collieries also make beans, say about ⅝ in. to ⅜ in. and peas, say about ⅜ in. to $\frac{3}{16}$ in. The dimensions may signify plate screens with round or with square holes, bar screens or wire gauze; in the two latter they may be measured in the clear or centre to centre. All these different methods are in use.

With reasonably closely sized coal of whatever dimensions it is found that as ordinarily heaped the coal occupies 55 per cent. of the total volume of the heap.

METALLIFEROUS MINERALS.

By *metalliferous* minerals or *metallic* minerals are meant those minerals that are technically utilisable for the extraction of the ordinary commercial heavy metals, metals of the alkalies and alkaline earths being excluded; this is almost identical with the meaning of *ores*, or with Group II, of above classification. In United States of America and Canadian statistics, a wider meaning is given to *non-metallic* minerals, which includes all minerals not actually used for the extraction of metals, e.g. ochre, although this is an oxide of iron, because it is used as a pigment and not as a source of iron.

COMPOSITION OF MORE IMPORTANT ORES.

Name.	Formula.	Percentage of Metal.
Magnetite	Fe_3O_4	Fe 72·4
Hæmatite	Fe_2O_3	,, 70
Limonite	Fe_2O_3,H_2O	,, 60
Brown hæmatite	Hydrated ferric oxide, with 10–15 per cent. H_2O	,, 45–55
Siderite	$FeCO_3$	,, 48·3
Ilmenite	$(TiFe)_2O_3$	,, 30–40
Pyrites	FeS_2	,, 46·7
Pyrrhotite	Fe_7S_8	,, 60·5
Pyrolusite	MnO_2	Mn 63·3
Manganite	$Mn_2O_3H_2O$	,, 62·5
Wad	Impure hydrated manganese oxide	,, 25–50
Chalcopyrite	$Cu_2SFe_2S_3$	Cu 34·6
Chalcocite	Cu_2S	,, 79·8
Malachite	$2(CuO)CO_2H_2O$	,, 56
Cinnabar	HgS	Hg 86·2
Galena	PbS	Pb 86·6
Cerussite	$PbCO_3$	,, 77·5
Anglesite	$PbSO_4$	,, 68·3
Blende	ZnS	Zn 67

IRONSTONE.

Ironstone is the term applied to stratified or symphytic deposits workable for iron, iron ore to epactic deposits, veins or masses. Bessemer ore or hæmatite ore is generally understood to mean iron ore with less than 0·035 per cent. of phosphorus when the ore contains about 50 per cent. of iron. Such ores are usually quoted on a basis of 50 per cent. of iron, with a definite increase or deduction in price for each unit of iron above or below that figure, and a penalty for every unit of silica above a given percentage, often 8 per cent.

The yield of ironstone is often taken roughly at 2,000 tons per foot thick per acre.

HAEMATITES.

These weigh 3–3·5 tons per cubic metre in place, 2½ tons per cubic metre in mine cars, 2 tons per cubic metre stacked.

TABLE OF BRITISH MESOZOIC IRONSTONES.

Formations.			*Name of Ironstone.*
CRETACEOUS—Neocomian	Wealden	Lower Greensand	Seend, Wiltshire.
		Weald Clay	
		Hastings Sand	Sussex and Kent. Westbury, Wiltshire, Claxby, Lincolnshire.
JURASSIC	Upper Oolite		
	Middle Oolite	Corallian	Dover, Kent.
		Oxford Clay	Westbury, Wiltshire.

COPPER, TIN, LEAD AND ZINC ORES.

Copper, tin, lead, and zinc ores are usually sold by assay. The value is calculated on the current market price of the metal multiplied by the percentage of metal present less the percentage estimated to be lost in the operation of smelting; from the value thus found there is then deducted the 'returning charge,' being the estimated cost of smelting the ore, including the smelter's profit, etc. The following were the generally accepted (pre-war) methods :—

COPPER ORES.—Weight paid for is gross weight less moisture and less 1 per cent. draftage. Wet assay less 1 per cent. for ores assaying 3–4 per cent. (deduction varied proportionately for richer or poorer ores); for value per unit (1 per cent.) take 0·01 of price of best selected copper, less returning charge of 2*s.* 3*d.* to 2*s.* 6*d.*

Example.—Cargo of 1,000 tons ore assaying 4 per cent. copper, ¼ per cent. moisture. Net weight $= 1{,}000 - \left(\frac{1{\cdot}25}{100} \times 1{,}000\right) = 987{\cdot}5$ tons.

4 per cent. − 1 per cent. = 3 per cent. copper to be paid for.

Best selected quoted that day 82*l.* 10*s.* per ton = 16*s.* 6*d.* per unit, less 2*s.* 3*d.* returning charge = 14*s.* 3*d.* 3 units at 14*s.* 3*d.* = 42*s.* 9*d.* per ton of ore.

Value of cargo 987·5 tons at 42*s.* 9*d.* = 2,110*l.* 15*s.* 7½*d.*

LEAD ORE.—Weight paid for is net dry weight. Percentage paid for is dry assay less 4 units, on basis of soft foreign lead price in London, subtracting 40*s.* per ton for returning charge. Silver above 3 oz. per ton paid for at current rate for fine silver. Price is understood to be delivered smelter's works.

Example.—150 tons net of galena assaying 78 per cent. of lead and 5 oz. of silver per ton quotations being : lead, 20*l.* per ton; silver, 2*s.* 3*d.* per oz. Lead, 150 tons at (78 − 4) per cent. = 111 tons at 20*l.* = 2,220*l.*, less 150 tons at 40*s.* = 1,920*l.* Silver, 150 × (5 − 3) oz. = 300 oz. at 2*s.* 3*d.* = 33*l.* 15*s.* Total value of ore, 1,953*l.* 15*s.*

ZINC ORE.—Weight paid for is net dry weight. From percentage of zinc, as determined by wet assay, subtract 9 units, multiply by $\frac{18}{20}$ of price of spelter, and subtract returning charge of 3*l.*; difference is price per ton delivered smelter's works.

Example.—If ore assays 50 per cent., London quotation for spelter being 18*l.*, the ore is worth £ $\left(\left[\frac{50-9}{100} \cdot \frac{18}{20} \cdot 18\right] - 3\right) = 4l.\ 0s.\ 3d.$ per ton.

The general gangue of most ores is quartz; solid quartz averages about 165 lbs. per cub. ft. (13½ cub. ft. to the ton), broken about 100 lbs. (22½ cub. ft. to the ton), but varies considerably. the weight of veinstuff containing metalliferous minerals can be calculated from the specific gravity of the minerals.

TABLE OF SPECIFIC GRAVITIES AND WEIGHTS PER CUBIC FOOT OF MINERALS.

Mineral.	Sp. gr.	Cwts. per cub. ft.	Mineral.	Sp. gr.	Cwts. per cub. ft.
Copper pyrites	4·1–4·3	2·34	Ilmenite	4·5–5·0	2·64
Copper glance	5·5–5·8	3·15	Hæmatite	4·5–5·3	2 73
Malachite	3·7–4·0	2·20	Brown hæmatite	3·4–4·4	2·17
Cinnabar	8·9–9·0	5·00	Spathic ore	3 4–3·9	2·04
Galena	7·3–7·7	4·18	Pyrolusite	4·8–4·9	2·67
Cerussite	6·4–6·5	3·60	Cassiterite	6·4–7·1	3·76
Anglesite	6·1–6·4	3·50	Wolfram	7·1–7·6	4·12

Stibnite	4·5–4·6	2·50	Calcspar	2·5–2·8	1·50
Pyrites	4·8–5·2	2·78	Dolomite	2·8–2·9	1·56
Mispickel	6·0–6·4	3·45	Fluorspar	3·0–3·2	1·73
Magnetite	4·9–5·2	2·80	Felspar	2·5–2·8	1·50

A rib of mineral 1 in. thick = 3 cub. ft. per square fathom.

Calculation of Mineral Mixtures.

The percentages of two minerals present in a mixture can easily be calculated if the sp. gr. of the mixture and of the ingredients is known. A convenient method is that proposed by R. T. Hancock.

Take a weight of x grms. of the mixture containing two ingredients of sp. gr., a and b respectively, where $\frac{1}{x} = \frac{1}{a} - \frac{1}{b}$ or $x = \frac{ab}{b-a}$; then the volume of this weight of a alone will differ from that of the same weight of b alone by 1 c.c., and for every 1 per cent. of a (the lighter substance) present in the mixture, the volume will be greater by 0·01 c.c. than the volume of b alone and for every 1 per cent. of b present, less by 0·01 c.c. than the volume of b alone. It is usually convenient to take $10x$ grms., when the differences will be 0·1 c.c.

Example.—To determine percentage of cassiterite (sp. gr. 7) and 'black sand' (sp. gr. 4·5) in a mixture of these. Since $\frac{1}{4{\cdot}5} - \frac{1}{7} = \frac{1}{12{\cdot}6}$, take 126 grms. Volume of mixture, measured by pouring the mixture into a burette partly filled with water and noting the difference in the burette readings, = 20 c.c. Volume of 126 grms. of black sand would be $\frac{126}{4{\cdot}5} = 28$ c.c. Hence percentage of cassiterite = 10 (28 − 20) = 80 per cent.

BORING.

Boreholes are put down by one or other of the following methods :—

I. Percussive:
- (*a*) Using solid rigid rods.
- (*b*) Using ropes.
- (*c*) Using hollow rods (water-flush method).
- (*d*) Using a hydraulic ram.

II. Rotary:
- A. Core drills.
  - (*a*) Using diamonds.
  - (*b*) Using steel cutting teeth.
  - (*c*) Using chilled shot.
- B. Hydraulic rotary oil drill.

Generally speaking, percussive methods are used when the primary object is to get a hole down rapidly, where information as to the nature of the ground passed through is of less importance, whilst rotary core drills, by the use of which a more or less continuous core is obtained, are employed when an accurate knowledge of the strata passed through is the first consideration. Sometimes both methods are combined; thus in some of the boreholes put down in Kent, boring through the secondary rocks was performed by percussion, whilst rotary core-boring was substituted after the coal measures had been reached. Percussion boring by the ordinary 'English' method can be used to depths of about 500 ft., costing about 10*s.* to 20*s.* per foot, and advancing 2 ft. to 6 ft. per twenty-four hours. Beyond this depth a free-falling cutter must be used, and in this way depths of 3,000 ft. or more may be reached.

Rope boring with round ropes on the American system is used almost exclusively in boring for oil, salt, etc. The plant for a hole 2,000 ft. deep would weigh about 80 tons complete and cost about 2,000*l.*; holes range from 6 ins. to 15 ins. in diameter. In Pennsylvania and Ohio such boring has been done for as little as 2*s.* per foot, and contracts are usually let at prices ranging from 4*s.* to 8*s.* The rate of boring is from 20 ft. per day upwards. In Middlesbrough, 8-in. holes have been put down to depths of about 1,000 ft. at a cost of about 8*s.* per foot with a speed of 60 ft. per day. Boring with flat ropes by the Mather and Platt system is used for very large boreholes, as for instance for waterworks; holes up to 45 ins. in diameter have been bored by this method.

The water-flush method, of which there are many varieties (Fauck, Raky, etc.), is used in hard rocks for boreholes of medium size (rarely under 8 ins. in diameter). Very fast boring can be done in this way; e.g. in the Ruhr district a borehole was put down to a depth of nearly 2,000 ft. at an average speed of 157 ft. per twenty-four hours; 30 to 50 ft. is quite a usual rate down to depths of about 2,000 ft., and over 20 ft. a day has been bored down to a depth of over 3,000 ft.

The hydraulic ram method appears to offer certain important advantages, especially for boreholes of moderately large diameter, but has hardly passed the experimental stage.

Core Boring.

Diamond boring is in use to-day for hard rocks; the main drawback is the high price of the 'diamonds' (bort, used in the softer rocks, costs 2*l.* to 3*l.** per carat, carbon costs 6*l.* to 12*l.* per carat), which tells severely against boreholes larger than 6 ins. in diameter. The cost of diamond boring in this country is about 7*s.* 6*d.* per foot down to 500 ft. and 12*s.* to 18*s.* down to 1,500 ft. for a 5-in. borehole. A 5-in. borehole put down in Scotland to 1,800 ft. cost only 6*s.* 4*d.* per foot; the rate of advance was about 6 ft. per day. In British Columbia a borehole 2,200 ft. deep cost 8*s.* 6*d.* per foot, and was bored at the rate of 10 ft. per day. In Victoria the Government does much boring to aid prospectors; the bores are mostly shallow, but in

* All costs throughout this article refer to prices before 1913.

one case a depth of 1,110 ft. was reached in about 120 days; the average cost of boring in coal measures in 1912 was 9*s.* 3*d.* and in the harder rocks 14*s.* per foot. In Nova Scotia 2 in. diamond boreholes put down by the Government in moderately hard ground to depths of 200 to 400 ft. averaged about 9*s.* per foot in 1913.

Steel cutting teeth can only be used in tolerably soft ground. The cutter should make 15–25 r.p.m. A 10-in. borehole in Kent was put down by this method by the Calyx Company to a depth of 1,400 ft., the speed at times reaching 10 ft. per hour.

The chilled shot method is very generally applicable, and is used for relatively large bore holes in hard ground. The cutter should run at 100–150 r.p.m.; about No. 5 shot is generally used. It is usually somewhat slower but cheaper than diamond boring. The consumption of shot with a cutter 4½ ins. in diameter ranges from 0·15 lb. per foot bored in shale to 1·2 lbs. in hard sandstone, but may be much higher in broken ground, where shot escapes into the fissures. In Nova Scotia 6 in. Government boreholes by this method averaged 10*s.* 6*d.* per foot in 1913.

The hydraulic rotary drill is the name given to a form now much used in boring oil-wells; it cuts out the whole of the material, leaving no core, the debris being brought to the surface by a water-flush. Over 100 ft. per day has been bored by this method.

Location of Bore-holes for Valuation of Alluvial.

When ground is systematically tested by pits or boreholes at regular intervals, three conventional views are possible:—

1. That there should be so many pits or holes per acre, or
2. That the distance between pits or holes should be so much, or
3. That no point on the ground should lie beyond a certain distance from a pit or hole.

The first two are those most generally held, but the last seems the most logical, and to attain it with the least amount of work the holes should lie at the corners of a series of equilateral triangles, the length of whose sides, or the distance of the pits apart, is equal to the maximum distance under condition (3) multiplied by $\sqrt{3}$. A line is run in any desired direction and staked at intervals equal to the distance between pits. From these stakes lines are turned off at angles of 60° or 120°, and staked at similar intervals starting from the turning-off point. The stakes are numbered to indicate their position on their own line and the number of the turning-off point, so that the pits sunk at them can be readily identified.

The advantages of this method over the more usual square lay-out are considerable. There is 6 per cent. less work involved in the lay-out of the holes, and 23 per cent. less in the sinking and sampling. The computation of values can also be more accurately done. Interpolation of values can be done on the plan, much as in contouring from spot levels, and a reliable assay plan prepared. (*R. T. Hancock.*)

The following is a list of some of the more important boreholes in the world:—

	£ *s.* *d.*
Lake Well, nr. Fairmont, Marian Co., W. Virginia .	7,579 ft.

Wheeling, West Virginia . .	4,500 „
Balfour Main, Fifeshire . . .	4,060 „

Drilling Shot Holes.

Performed by hand, either by jumper for moderately hard rocks, by hammer and drill for hard rocks, or by the coal miner's hand machine, now used almost exclusively in coal and very largely in ironstone (W. Charlton, *Trans. Inst. Min. Eng.*, 1902, vol. xxiv., p. 526). Average rate of boring is 4 to 8 ins. in bituminous coal 2 to 4 ins. in shale, per minute.

'Mushrooming' of shank end of drill causes loss of 20 lbs. steel per man per annum. Tempered pear-shaped shank ends are being used at East Rand Proprietary Mines. (*Journ. Chem. Met. and Min. Soc. South Africa*, 1919, vol. xix. p. 168.)

Mechanical Drilling.

Also either rotary or percussive. Rotary drills mostly of the twist-drill type confined to the softer rocks; Steavenson electric drill averages 40 ins. per minute in ironstone, uses 6 h.p. Siemens and others make small electric drills, taking 1 to 2 h.p., boring 6 to 10 ins. per minute in coal. For boring in hard rock the Brandt machine has been used in the Simplon tunnel and in some German collieries; hydraulically driven under head of 1,500 lbs. per sq. in.; bores 15 ft. per hour in gneiss. The Kellow drill used in North Wales is similar; has drilled 5 ft. per minute in slates.

Percussive drills are almost exclusively worked by compressed air. The drills are of two kinds: piston drills, in which the drill bit is rigidly connected with the piston rod, and hammer drills, in which the piston rod strikes on the end of the drill bit, the latter being lighter, smaller, and running at much higher speeds.

Drills may be classified by their valve action:—

1. Valve moved by external tappets.
2. " " internal "
3. " " air with auxiliary valve moved by tappet.
4. Valve moved by air.
5. Valveless, the piston itself acting as a valve.

Most modern drills belong to Class 3, but several types belonging to Classes 2 and 4 are also in use; very many hammer drills belong to Class 4.

Piston drills are further classified by their piston diameter, ranging from 2 to 4 ins.; 2¼-in. drills are largely used for stoping, 2½ to 3½ ins. for drifting, 3 to 3½ ins. for sinking. In 1902 70 per cent. of the drills in use on the Rand were 3½ drills. Such drills use 60 to 90 cu. ft. of free air per minute at pressures between 60 and 90 lbs. per sq. in. A 3-in. drill evolves about 1¾ h.p., for which about 5 h.p. must be applied to the drill piston and 10 to 25 h.p. to the steam end of a direct-driven air compressor.

At the Rose Deep Mine, Transvaal, a trial run of 31 drills for 6 hours gave air consumption for 3¼-in. drills 81 cu. ft. compressed air, free air compressed to 70 lbs. pressure per minute; each drill required the consumption of 43 lbs. coal per hour to supply this air, 3·4 lbs. coal developing 1 h.p. hour. The average power of the compressor engine was 12·7 i.h.p. per drill; average drilling speed 4·5 ft. drill hole per drill per hour.

Relative air consumption of drills:—2½-in. drill, 0·445; 3¼-in. drill, 1·000; 3 5/16-in. drill, 1·069; 3⅝-in. drill, 1·123.

Average speed of boring, including setting up, is 10 to 25 ft. per 10-hour shift. Costs of boring in hard rock in Sweden are about 8*d.* to 10*d.* per foot bored, of which 40 per cent. is for wages and 30 per cent. for power; average boring speed is 5 ft. 6 ins. to 8 ft. per hour for downward holes and 4 ft. to 6 ft. 6 ins. for upward holes.

Hammer drills use 25 to 50 cubic feet of free air per minute; speed of boring about the same as piston drills, but holes are usually smaller. Hammer drills with a relatively rapid turning action of the bit and using bits with a chisel edge, but specially twisted steel, are used very successfully in coal.

A complete 6-piston-drill plant costs about 500*l.*

Two-stage compressors, delivering air at 100 lbs. gauge pressure, weigh on the average 27 lbs. and cost on the average 12*s.* in the U.S.A. per cubic foot piston displacement.

Sharpening Steel Bits.

A good blacksmith and striker can sharpen 30 to 40 bits per hour.

By the use of power drill-sharpeners, many of the shortcomings attendant upon the hand-sharpening process are got rid of, and drills can be kept true to gauge, with the result that where these machines are used it is possible to accomplish more drilling, whilst the cost of sharpening is considerably reduced.

According to experiment, the fastest cutting bit is the Carr (double chisel bit with central hole), the Z, + and 6 edged star in this order; cutting speed $\propto$ (drill diameter)$^{-2}$; cutting speed $\propto$ air pressure; pressure of 85 lbs. per square inch most generally satisfactory.

(*Bull. Amer. Inst. Min. Eng.*, August 1917, p. 1079.)

The Leyner compressed air operated drill sharpener, which can be handled by one man, is capable of sharpening up to 100 drill bits per hour, the number depending upon the size of the bits and steels to be handled.

In the case of small quarry plants or contract work, where drilling is done in the open, dry steam at a pressure of from 80 to 100 lbs. can be used, but will not give such good results as compressed air. Where a number of drills are used, a compressed air plant should preferably be installed, and is indispensable in underground drilling. With a properly laid pipe line of suitable size, there is very little loss in conveying compressed air from a central plant over very large distances.

Holman Pedestal Grinder.

(Holman Bros., Ltd., Camborne, Cornwall, England.)

With these grinders (fig. 1) it is possible to keep the shanks of drill steels straight and true in addition to trueing up the edges of drill bits and repointing picks when necessary. The machines can be used as general workshop grinders for all kinds of tool grinding.

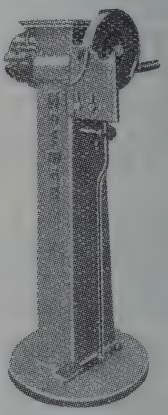

Fig. 1.

The machine does not require any foundation, but will stand wherever required, and is easily moved from place to place.

The machine provides a very economical means for cheap grinding, as it only uses power while the foot control is depressed and when released stops immediately. Full power and speed are attained immediately it is started.

The 'Holman' Drill Steel Sharpening Machine.

(Holman Bros., Ltd., Camborne, Cornwall, England.)

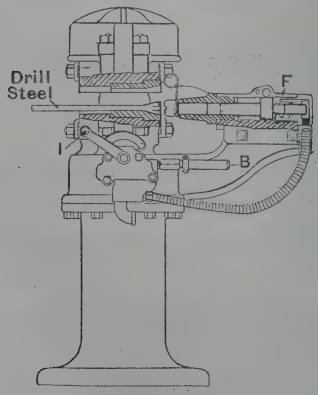

Fig. 2.

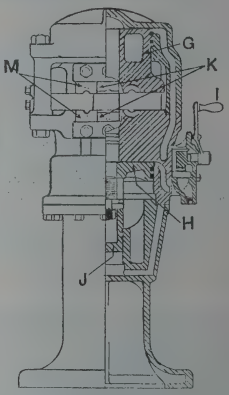

Fig. 3.

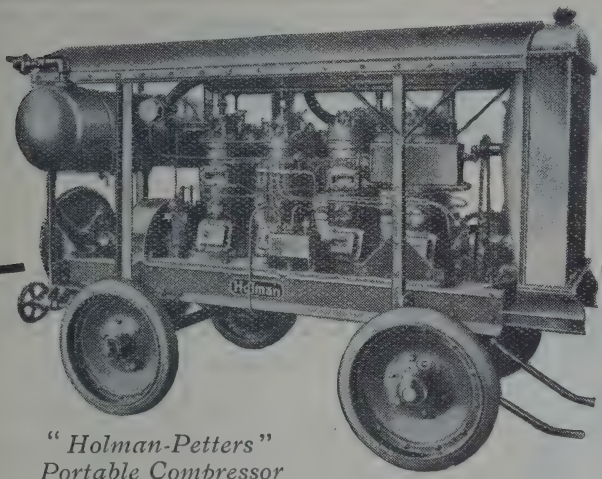
This drill sharpener is used to make various types and sizes of drilling bits for rock-drilling machines.



"Holman-Petters"
Portable Compressor

Holman Portable Compressors

mean

—an ample power supply on the scene of action—in fact wherever wheels can travel; years of efficient service from each machine, because the Holman Portable is free from the deterioration to which high-revolving machines are subject; and above all, *an upkeep charge that is well within your estimated requirements.* One of the types listed below will be right for the work in hand, and will go a long way towards lessening costs.

PETROL DRIVE

Lubrication system has been designed to be entirely automatic. Air control valve regulates output according to consumption. Reliable 4-cylinder engine. 2-cylinder Compressor unit. Whole machine is sturdy, compact and completely self-contained, and can safely be left to unskilled hands. Shuttered sides.

ELECTRIC DRIVE

When connected to a suitable source of current supply, will run for long periods with the mere additions of oil and water. Equipment entirely self-contained. Shuttered sides. Eminently suitable for unskilled hands. Compressor unit and gearing entirely enclosed. Working costs are very low.

CRUDE OIL DRIVE

Suitable for working on all crude and residual oils or refined petroleum; in economy alone it shows a distinct advancement.

Valves are eliminated from the 2-cylinder 2-stroke engine, and upkeep charges are less than half those of engines having a four-stroke cycle.

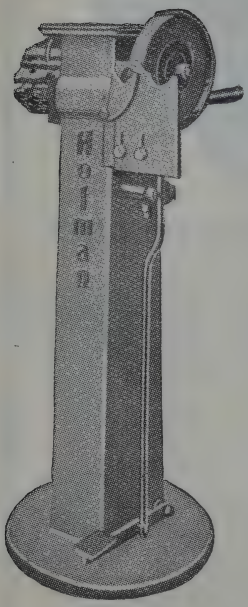
Portable Grinder

Holman Pneumatic Tools



Pedestal Grinder

Portable Grinder

Owing to its efficiency and portability, this machine is finding great favour in workshops and for all trade purposes.

The construction of the motor follows very closely that of our Air Drills. The design of the Crankshaft construction and the Roller Bearing ends has overcome overheating.

Our crankshaft runs more or less frictionless, and each machine under test has to run under full load and at free speed for four hours continuously before being passed out.

Pedestal Grinder

In rock drilling operations where hammer drills are used, it is essential that the shanks of drill steels are kept the correct size, and the ends square true with the axis of the steel, otherwise piston breakages will be common.

When these grinders are supplied as standard equipment with Drill Sharpeners, steel breakages due to improper shanking will quickly vanish, as it is possible to keep the shanks straight and true in addition to trueing up the edges of drill bits and repointing picks when necessary. The machines can be used as general workshop grinders for all kinds of tool grinding.

The machine requires no foundation.

EXAMPLE.—Required the amount of free air necessary to operate thirty 5-in. 'H' drills at 9,000 ft. altitude, using to operate these drills air at a gauge pressure of 80 pounds per sq. in.

From Table I we find, when operating the drills at 80 pounds gauge pressure at sea level, that one 5-inch 'H' drill requires 190 cubic feet of free air per minute.

From Table II we also find that the factor for 30 drills at 9,000 feet altitude is 20·38; multiplying 190 cubic feet by 20·38 gives 3,872 cubic feet air per minute, which is the displacement of a compressor for the above outfit under average conditions, to which must be added pipe line losses, such as friction and leakage.

In the first operation the heated steel is placed in the grips (fig. 2), the steel being held in one hand, the control handle in the other. This handle is pushed forward slightly, admitting air to the pistons G and H (fig. 3), which grip the steel. A further forward movement of the handle I operates the dolly hammer F and forms the rough shape of the bit. The handle is then returned to its original position, piston J lifts the grips and releases the steel, which is then transferred to the forming dies K (fig. 3). By a few quick movements of the control handle, air is admitted to one of the pistons only, to form the cruciform section. The operation is repeated until the bit is a little oversize and at an angle of 15°. The bit is then transferred to the sizing dies M and M, where a couple of blows finish it to the required diameter and give the clearance angle of 5°.

An important feature of this machine is that whilst both cylinders are used to give a powerful grip to the steel, only one is needed for ordinary swaging operations, unless a very heavy blow is required, in which case both can be used. All operations in making bits or shanks are obtained by movement of one control handle.

This is a Holman Patent (No. 5452) of 1924.

Notes on Rock Drills.

In mining practice, drills are required to be of rapid boring capacity, and at the same time of light weight, so that the work may be both rapidly advanced and the whole outfit moved in awkward places with a minimum of trouble. In driving main headings, the piston type of drill, mounted on columns, is generally used. Where space is limited, it is not uncommon to mount two drills on arms attached to one column, two runners and a helper being sufficient to handle the machines so arranged; in large tunnels the drills, from 1 to 4 in number, and of heavy pattern, are frequently mounted on drill carriages, thus enabling the equipment to be rapidly moved away from the face when the round of holes is ready for firing, without the necessity of dismantling. In stopes, raises, or small headings, the telescope-feed hammer drill, which is largely used, is a one-man drill, and is a rapid boring machine. Where the rock is of such a nature as to cause a considerable amount of dust, a condition which is to be met with in almost every metalliferous mine, drills having an automatic water feed are used. In the case of the heavy drills, the water is fed through the piston and drill bit under pressure; of this type is the Leyner-Ingersoll. Telescope-feed stope drills can also be arranged for water feed through the heads and drill bits, which have a central hole running from the shank to the cutting face for this purpose.

For hammer drill work, drill bits are furnished with single chisel, double chisel, 6 point and 'Z' cutters, the steels themselves being sometimes hollow and sometimes round, hexagonal or spiral, the section depending upon the class of rock to be bored.

Compressed Air Drilling Plants.

The Hardy-Simplex Air Hammer Rock Drill (*Patent*).

(*The Hardy Patent Pick Co. Ltd., Sheffield.*)

In this drill, fig. 4, the valve action is as follows:—When the air pressure is suddenly reduced at one end of the valve, the piston uncovers the main exhaust ports, and the full pressure acting on the opposite end causes the valve to travel to the other side of the valve box and thereby change the direction of the air pressure and reverse the piston or hammer. The action of the valve does not depend on compression set up by the piston in order to accomplish its reversal. It is not dependent on a tight piston and cylinder. It moves only $\frac{1}{64}$ in. in order to cut off the main air supply, but it has a further considerable travel before readmitting air. By the arrangement, all valve losses are practically eliminated, and the delay in readmitting air in quantity for the reversal of the piston diminishes internal resistance, so that a very powerful blow is given with a very small air consumption.

The valve will preserve its air tightness practically indefinitely, whilst at the same time it is perfectly balanced, and so light as to have great rapidity of action. The cylinder and valve box are forged together in one piece of special steel, bored, case-hardened to a glass hardness, and then accurately ground. The valve and valve bush are both manufactured from special alloy steels, both parts being hardened to suit the demands made on them. The rotation is effected by means of a rifle bar and a ratchet wheel situated at the rear of the machine in combination with a number of straight grooves cut in the piston or hammer working through a steel guide nut, situated in the chuck or drill holder. All parts of the rotation device are of hardened steel and are readily renewable.

The drills are retained by means of a cap which is provided with a strong round thread screwing over the front of the drilling machine and embracing the collar on the drill shank. The cap is slotted its full length, thereby enabling the machine to be at once disengaged from the drill steel should this for any reason become necessary.

The drills are made in three sizes, viz., the B5, B6, and B7, weighing 23 lbs., 27 lbs., and 40 lbs. respectively. The B5 pattern is for all overhead work in any class of rock; it is also used for coal boring on long wall faces and in headings, etc. The B6 pattern will bore easily

oles up to 10 ft. in depth where necessary, in rock of any hardness, the speed of boring varying rom 6 to 8 ins. per min. in hard granite to 30 ins. per min. in soft sandstone, and up to 48 ins. er min. in hard coal. Air at 60 to 80 lbs. per sq. in. The B7 pattern has been designed specially

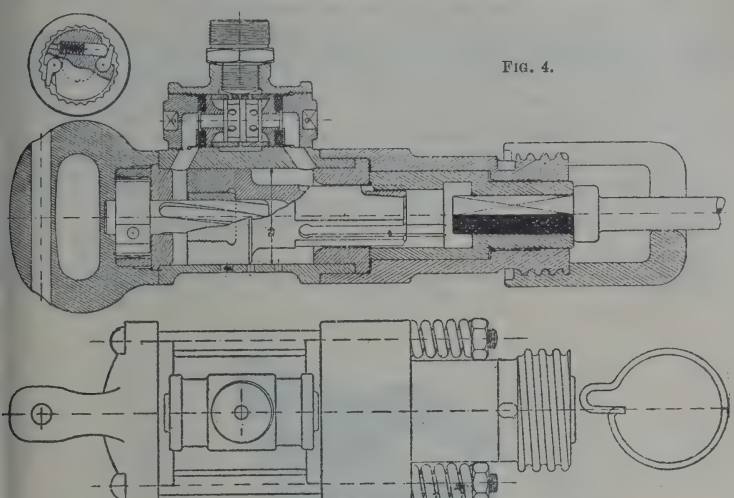

FIG. 4.

or 'down holes' in very hard ground in mine shafts and in quarries. It will easily drill holes p to 25 ft. in depth, starting at 3 ins. in diameter. Its normal boring speed in hard granite is to 10 ins. per min. with air at 80 lbs. per sq. in.

THE HARDY AIR COMPRESSOR.

(Patent.)

(*The Hardy Patent Pick Co., Ltd., Sheffield.*)

This compressor is of the vertical single-acting type, single stage. The idea has been to rovide a first-class small compressor of a simple type for driving rock drills, pneumatic ammers, etc., for use in mines, quarries, and engineering shops, and for such purposes up to 80 r 90 lbs. pressure per sq. in.

The lubrication of the whole machine is purely automatic and on the 'splash' principle.

The special feature of this compressor is the valve system. The inlet valve is situated in the iston itself, and consists of a simple ring controlling an annular inlet port in the piston head. his valve opens instantly on the down stroke, and remains open practically until the precise noment when the piston is reversed, admitting air both on its inside and outside peripheries nd thereby ensuring a very high volumetric efficiency. The great port opening combined with he absence of spring load, gives an unbreakable inlet valve with a maximum port area and a ninimum of complication.

The discharge valve is of the same ring type, made like the inlet valve of a special metal but louble-ported and spring-loaded for quick closing to prevent reflux of compressed air after lischarge. The discharge valve also uses both inside and outside peripheries, giving an ample ort area to prevent undue excess pressure at the moment of discharge. The springs are seated artly in the discharge valve guard and partly in grooves in the discharge valve. They are ery light and simple, and may be relied upon to give satisfactory service.

The water-jacketing of the cylinder walls is very thoroughly carried out and results in cool working and moderate discharge temperatures, thereby ensuring a high over-all efficiency of ompression. The cylinders are of high-grade iron, crank and connecting rod of forged steel, f full dimensions; large inspecting doors and oil reservoirs are provided. In action the ompressor is almost silent.

All machines are now fitted with automatic shut-off valve, closing the suction as soon as the lesired pressure is attained; this reopens only when the pressure falls.

The compressors are made in three sizes, giving capacities of 50, 75 and 140 cu. ft., respectively

The Holman Light Drifter.

(Type 'P.V.' 160.)

(*Holman Bros., Ltd., Camborne, Cornwall, England.*)

This drill is the latest Holman product, and is the fastest and lightest the firm has produced. Designed on standard lines, with every detail improved and several original features added, the new 'P.V.' marks a distinct advance in rock drilling practice, and may be taken as the last word in simplicity of design, reliability under practical conditions, and absence of dust in drilling.

The flap valve, although simple in construction and design, is highly sensitive, thus ensuring the greatest economy in air consumption. Two valves of the same type, but smaller, deal with the compression, enabling the piston to strike with full force and increasing the number of blows.

Among the particular advantages of the new mechanism are: the adjustable cone, and the full length cradle slide, which are important factors in drilling the maximum number of holes per shift. In ground where the 'gauge' of the bit is not seriously affected, 68 ins. in depth can be drilled with one steel. It is also useful in withdrawing the steels.

The standard type cradle can be supplied with a 42-in. feed, when required for exceptional conditions.

Another feature of this drifter is its improved water system for allaying dust. All that skilful design can do in this direction has been done, with the result that the formation of dust is absolutely impossible.

'P.V.' Drifter Valve Mechanism.

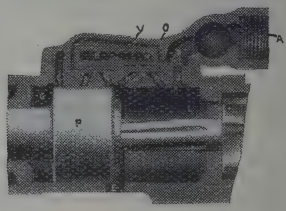

Fig. 5.

Air entering A (fig. 5) passes over the valve V to ports B and C, and moves the piston rearward. When the piston slightly opens the main exhaust E the valve lifts, and air enters port J and throws the piston forward.

Meanwhile the hollow under-face of the valve is charged with live air through ports S, which lifts it immediately the opposing pressure is reduced by the exhaust.

The air then passes under the valve, locking it in position until the exhaust slightly reduces the pressure, when the live air acting on the area of the valve projecting from the bridge and covering port J, instantly closes it, and the movement is reversed.

The compression during the above operations is dealt with by the release valves K and F which are automatically lifted by the air compressed before passing out at ports R and H.

These valves are alternately air locked by ports O and N when not in use.

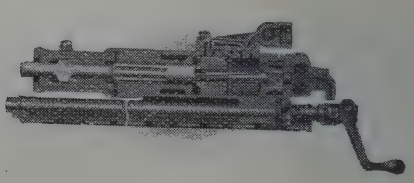

Fig. 6.—Section of Holman Light Drifter showing general arrangement of drill, also air vent at the piston point, to prevent the formation of dust. The back end shows a large oil well for lubricating the ratchet gear twist bar and nut.

For 'Holman's' Single-Stage Air Compressor, see p. 1260 ,and for 'Holman's' New Rotary ir Compressor, see p. 1261.

Metallic Tubing.

Flexible Metallic Tubing (*The United Flexible Metallic Tubing Co. Ltd.*, 112 Queen Victoria treet, London) is specially suitable for mining work. Its durability renders it economic, and it minishes 'breakdowns,' as the tubing cannot kink and is not easily crushed ; it is also unaffected y changes of atmosphere, or by vermin, white ants, etc.

Wire Clamping Tool for Compressed Air Hose.

Fig. 7 shows a tool in use in a number of the mines for winding wire around the hose to hold ie nipple in place, thereby doing away with the usual clamps and bolts.

The dimensions given are approximate for a tool used in clamping a 1-in. four-ply hose. On ie end of a piece of ¾-in. pipe 6 ins. long a standard pipe thread is cut, and on the other end a -in. bolt thread about 3 ins. long. The end with the bolt thread is inserted in the hose about ins., and the hose is ready for the wire clamping.

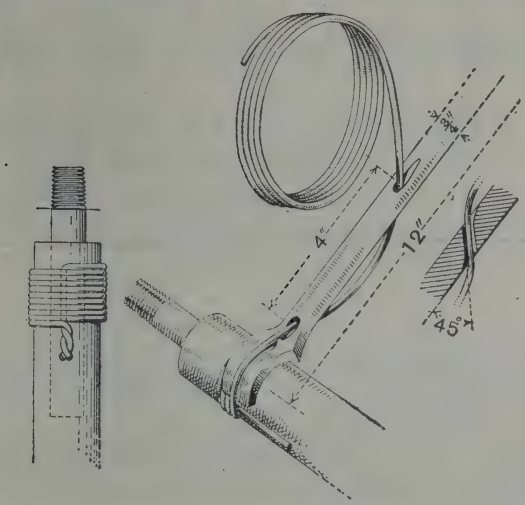

Fig. 7.

A No. 14 Stubs gauge soft steel wire is used. The wire is cut in 9-ft. lengths for winding a -in. hose, shorter lengths being used for smaller hose. The wire is first wound up on a piece f 3-in. pipe with a slot cut in it so that the wire can be hooked in it and held in place while the undle is being wound. When a hose is to be clamped, a bundle of wire is taken and started on he tool as shown in the figure. The wire is fed through the tool until about 4 ins. extends beyond he point of the tool ; this is then bent at a right angle, and is laid on the hose lengthwise. The ire is then wound around the hose layer after layer, and when the final turn is made the two ends re given two twists and the job is done. Any number of lengths of hose may be connected in his manner. The two holes through the handle are drilled at an angle of 45 deg., which gives the roper tension to the wire when winding.

(See also p. 1155.)

Air Receivers.

An air receiver is not intended so much for storage as to equalise pressure, and to allow of n even flow of air through the pipe, there being a certain amount of pulsation from the air ompressor discharge itself. In long pipe lines a smaller receiver should be placed in the pipe ine near the point of application of the compressed air, furnished with suitable drain cocks, for he purpose of drawing off the superfluous moisture which might collect, and the consequent

prevention of freezing in the line. The following table gives sizes and details of receivers which are usually considered standard practice :—

TABLE III.—AIR RECEIVERS AND PRESSURE TANKS FOR STANDARD WORKING PRESSURES. Tested to 165 lbs. Water Pressure.

Diam. in Ins.	Length in Ft.	Contents Cub. Ft. (about).	Thickness of Shell. Ins.	Thickness of Heads. Ins.	Weight Lbs. (about).	Diam. of Safety Valve. Ins.	Diam. of Inlet and Discharge Openings. Ins.	Compressor Capacity Receiver is Best Adapted for in Cub. Ft. Free Air per Minute.

(For Air Compressors see p. 1254.)

BLASTING.

Explosives are divided into low explosives, with a slow rending action and fired by simple ignition, and high explosives, with a rapid shattering action, fired by means of a detonator. The rate of explosion of gunpowder, typical of the former, is 3 to 4 metres per second, and of blasting gelatine, typical of the latter, up to 7,000 metres per second.

For blasting in fiery coal-mines explosives known as safety explosives are employed, which have a lower temperature of detonation. No explosive can, however, be considered really safe in a fiery atmosphere. In this country only those explosives are allowed to be used that have passed the Government tests and which are scheduled in the Home Office Order in force for the time being. A shot-hole in coal should never be placed in the solid, i.e. in coal that has not previously been kirved.

If D be the depth of a properly placed shot-hole, the volume of rock blasted out averages with one free face $0{\cdot}37\ D^3$; with two free faces volume $= 0{\cdot}84\ D^3$, and with three free faces $1{\cdot}33\ D^3$. In drifting and shaft sinking the volume blasted out is approximately $0{\cdot}75\ D^3$. If L be the line of least resistance, D=about 1·75 L.

The quantity of explosive required for charging a shot-hole may be calculated by the following formula, modified from Chalon :—

Let Q be the quantity of explosive in lbs., L the line of least resistance in feet, then

$$Q = \epsilon \kappa L^2,$$

where ϵ is a coefficient depending on the explosive and κ a coefficient depending on the character of the rock.

VALUES OF ϵ.

Blasting gelatine	0·14	No. 3 dynamite (33 per cent. nitroglycerine)	0·3
No. 1 gelatine dynamite	0·20		
Tonite	0·245	Compressed powder	0·4
Roburite, bellite and similar 'safety' explosives	0·25	Ordinary blasting powder	0·6

Low-tension electric fuses require a tension of about 1 volt; medium, about 4 volts; high, bout 100 volts. Low tension fuses best in series, high tension in parallel.

Liquid air is used extensively in the ironstone mines of Lorraine; a cartridge containing saw-ust, powdered cork, soot, or a similar substance impregnated with liquid air or liquid oxygen is mployed. The addition of aluminium powder to the charge greatly increases the detonating action. The uantity of liquid air used is 0·3 litre per ton of ironstone, and the cost of this explosive per ton lasted is given as 0·303 per cent. as against 0·571 per cent. with cheddite and 0·597 per cent. ith compressed black powder. Liquid oxygen is preferred to liquid air, because the latter is pt to produce fumes containing oxides of nitrogen which injuriously affect the miners, whereas ith the former no noxious gases at all are evolved.

Under Explosives Order No. 1194 of 1921, the production in the mine of an explosive by npregnating carbonaceous material with liquid air or oxygen is now permitted under licence, hus modifying Section 50 of the Explosives Act, 1875.

Detonators.

Detonators.—These are known by numbers, the charge of which varies somewhat. The ollowing is about the average practice:—

Detonator numbers	1	2	3	4	5	6	7	8
Weight of mixture in grains	4½	6	8	10	12	15	23	30

The mixture consists of 80 per cent. fulminate of mercury, 20 per cent. chlorate of potash.

Detonating Cord (Cordeau détonant) consists of a flat tube of lead, tin or aluminium usually mm. wide, 3 mm. thick, filled with nitro-methylaniline or trinitrotoluol, containing usually bout 10 grams of explosive per metre. An explosion is propagated through this at a velocity f about 7,000 metres per second. A piece of this cord is attached along a row of blasting artridges and ensures their complete and instantaneous detonation, even in wet holes. It is tated that the efficiency of the explosive is increased by 20 per cent., and that experiments at levin have shown that an explosive mixture of firedamp is not ignited by the detonation of metres of cord.

Ordinary fuse burns at the rate of 30 seconds per foot.

(See also EXPLOSIVES, p. 2783.)

ELIMINATION OF MISFIRING OF CENTRE SHOTS.

As a means towards the elimination of misfiring of centre shots in large-scale blasting in oal mines, the United States Bureau of Mines recommends that the following practices be used henever shots are to be fired in wet holes: Use waterproofed electric detonators with enamelled eg wires. When making connections with enamelled leg wires, care must be taken to scrape he ends of the wires well, otherwise the enamel will prevent good electrical contact. Fire the hots from an ungrounded power circuit that has a capacity of at least 30 kw. Use extra care hen tamping the holes in order not to damage the insulation of the leg wires. Arrange the onnections between the detonators so that they are supported clear of the earth or any other onducting medium.

Drifts.

In collieries, drifts of ordinary size, say 35 to 50 square feet in sectional area in ordinary oal measures, range in price for hand labour in 1913 from 1*s.* to 2*s.* per linear yard for each square oot, according to nature of strata and width of drift, being less the wider the drift. The cost in hale is about two-thirds of the cost in ordinary sandstone. Mean rate of advance of such drifts, bout 4 to 6 yards per week in sandstone, 6 to 8 yards per week in shale, 3 shifts per day, two niners in face with two to three labourers.

For inclined drifts rising at high angles the prices will be up to 50 per cent. higher; for drifts lipping at a high angle up to 100 per cent. In very hard sandstone the speed of driving will e about one-half, and the costs about double those given above, and in hard tough igneous ocks, such as basalts, the speed may fall to one-fourth, and the cost rise to four times these figures.

By the use of rock drills the speed may be greatly increased, especially in hard rocks, but he actual drivage costs are not much diminished, except in the harder rocks.

In making height where a top or bottom canch of stone has to be blasted, the price for a top anch of shale ranges from 1½*d.* to 2*d.* per inch for a width of 6 ft.; sandstone, 2*d.* to 3*d.* Bottom anches cost about 20 per cent. more than top canches. These prices include stowing the stone.

Driving in hard carboniferous limestone drift 30 sq. ft. in cross-section cost about 60*s.* pe yard ; three men in three shifts can drive about 4 to 5 yards per week by hand. In one case wit hand-drilling the cost was 55*s.* per yard, and rate of advance 4 yards per week, and with machine drilling the cost fell to 25*s.* and the rate of advance rose to 10 yards.

In metalliferous mines.—*By hand.*—A drift 5 ft. by 7 ft. in the clear, in rock of medium hard ness, can be driven by hand at a rate of 30 to 40 feet per month by employing two ten-hou shifts per twenty-four hours. In soft rock as much as 100 ft. per month can be penetrated. Th cost in moderate rock with labour at 12*s.* per shift will average about 2*l.* per foot, includin timber and strap rails.

By machine.—A 5-ft. by 7½-ft. drift was run in Colorado, U.S.A., at the rate of 236 feet pe month. This speed is above the average and was due to a well-trained crew (three shifts pe day) working on a bonus system. Rock was granite, gneiss, and schist, very hard to drill an breaking badly. Labour, 16*s.* per shift. Cost, 2*l.* 14*s.* per foot.

At Cripple Creek, wages 13*s.* 6*d.* per eight-hour shift, ground moderately hard, 896 ft. of 5 ft by 7 ft. drifts were run by machines, at a cost of 1*l.* 4*s.* per foot ; 1,229 ft. of 5 ft. by 7 ft crosscuts were run at a cost of 1*l.* 9*s.* per foot.

At Park City, Utah, with miners' wages at 12*s.* per eight-hour shift, a timbered drift 7 ft by 11 ft. was run in quartzite by means of 3½ inch air drill, 3 shifts per 24 hours, at rate of 4·7 ft. per day. at a cost of 2*l.* 4*s.* per foot of drift, or 7*s.* 1*d.* per ton of material broken. No hoisting

At the same mine crosscuts 7 ft. by 7 ft. in the clear are run by air drills at a rate of 8 f per day at a cost of 2*l.* 15*s.* per foot or 15*s.* per ton of material broken.

The Chipeta Adit in Colorado, U.S.A., 7½ ft. by 7½ ft. in clear, was run in hard rock a distanc of 1,712½ ft. in 152 days. The best monthly average was 342½. Two 3½ in. air drills were em ployed. The cost, including track and pipe, power, timber, labour and explosive, was 2*l.* 4 per foot. The amount of powder (40 per cent.) consumed was 14½ lbs. per foot of tunnel. Wage 16*s.* per day.

In Western Australia the drifts vary in size from 5 ft. by 7½ ft. to 6 ft. by 7 ft., and the cross cuts from 5 ft. by 7 ft. to 8 ft. by 8 ft. In eleven of the principal mines the rate of driving an crosscutting varies from 25 ft. to 90 ft. per month, averaging 60 ft. Working costs rang from 46*s.* to 103*s.* per foot, averaging 60*s.* The total costs of drives were from 3*l.* 6*s.* to 4*l.* 2 per foot and crosscuts from 3*l.* 3*s.* to 3*l.* 14*s.* At the Braden Copper Mine, Chili, all developmen work in the nature of drifts, crosscuts and upraises with average section of 4·53 square metre are run at an average cost of 14*s.* per foot driven. This cost includes all labour (native Chilian supplies, explosives, machinery, and tramming. No timber is used. The work is done unde contract and rock is moderately hard and breaks well. Machine drills are used. The rate o progress is about 130 ft. per month or 13 ft. per month per man.

Timbering Drifts.

Props 3 ins. to 5 ins. diameter and crowntrees 5 × 2½ ins. are often used in colliery drifts ; i main roads balks of much larger size may be used.

Resistance to crushing of pit props in tons per square inch of small end :

Scandinavian white wood, 1½ ; Larch, 1½ ; Scotch Fir, 1¼ ; Oak, 1 ; Beech, 1⅜.

Prof. Hudson Beare gives the following :—

Scots Pine, 1·767 ; Spruce, 1·892 ; Larch, 1·871 ; Japanese Larch, 1·379 ; Finnish Re and White Wood, 1·784 tons per square inch of mean area of prop.

In main roads ferro-concrete props are coming into use ; their crushing strength is abou 1·3 tons per sq. in. Tests by W. A. Machin (*Trans. Nat. Assoc. Col. Man.*, xv., p. 155) gav 1·58 to 1·82 tons per sq. in. on Keedon props 6 ft. long, about 4½ ins. square.

Instead of balks, steel H girders are often used. The following are some of the usual sizes :

Depth by width, in ins.	6×6	6×5	6×4	5×4	4½×4
Weight in lbs. per linear foot	31	27	24	22	18
Tons that will be carried in middle by beam 1 ft. long, supported at both ends	160	130	120	105	60

Drystone arching for roadway 6 to 7 ft. high and 3 ft. to 4 ft. 6 ins. wide in Alston distric costs about 12*s.* 6*d.* per linear yard for labour. The cost of labour for ordinary arching range from 7*s.* to 10*s.* per linear yard. Concrete arching varies from 6*s.* to 10*s.* per cubic yard of con crete put in. Arches of steel H girders supporting galvanised sheets have been used successfull in big drifts.

A coating of magnesia cement on the timbers of mines is stated to be an economical and efficient assurance against fire, especially in the arid regions where timber becomes highly inflammable and is difficult to replace. It is elastic, adheres firmly to almost any surface, and is stable and durable.

A layer of cement put on by means of a 'cement gun' (p. 496) is sometimes used for covering timbers, also the sides and roofs of drifts, etc.

In drifts in very heavy ground the Schaefer system of lining may be used ; this consists o blocks of reinforced concrete, set dry, but keyed into each other, with rows of wooden blocks t take up the squeeze ; such linings may deform under heavy pressure, but will keep the drift open (*Trans. Nat. Assoc. Coll. Managers*, vol. xxiv., 1926-7, p. 122.)

SHAFTS.

Modern shafts are generally either rectangular or circular in cross-section; the former are sed in sinking upon narrow veins or seams, where the ground is not very heavy nor the amount water excessive, or where good timber is cheap; under other conditions round shafts are pre-rred, but local custom also exercises much influence. Inclined shafts are practically always ctangular; elliptical shafts have been sunk in some places (Forest of Dean) but are now rarely sed.

Rectangular Shafts.

Rectangular shafts for large mines may be up to 25 ft. long by 15 ft. wide in the clear. xceptionally large shafts are used in Pennsylvania, e.g., No. 5 Wilkesbarre anthracite mines, ; ft. by 12 ft., Exeter Red Ash, 46 ft. 2 ins. by 13 ft. 10 ins.

Round shafts, say from 8 ft. to 24 ft. diameter in the clear; a colliery shaft to wind 000 tons per day is usually 16 to 18 ft. diameter.

Rectangular shafts are mostly wood-lined; they are either cribbed or timbered with sets olding lagging in place. In Fifeshire shafts up to 30 ft. by 12 ft. are cribbed with 'barring' 9 ins. by 3 ins. up to 6 ins. by 12 ins. The timber for a shaft 23 ft. by 8 ft., including buntons, c., would amount to about 125 cubic feet, and would cost, including nails, wedges, etc., about 3*l.* 10*s.* per fathom. The cost of sinking (the ground is usually easy) and putting in the timber about 30*l.* per fathom. In the iron-ore mines of Cumberland and Lancashire shafts about) ft. by 5 ft. are cribbed with 10 ins. × 5 ins. plank, the ends being half checked; the total ost including sinking, timbering, timber, stores, etc., is about 30*l.* per fathom, the ground being arboniferous limestone that requires blasting. Sets are made of squared timber 4 ins. × 6 ins. r a small shaft, up to 9 ins. × 15 ins. for a very large one; sets are 3 ft. to 6 ft. apart, held gether by hook bolts of 1¼-in. round iron with wing nuts.

Horned sets or bearer sets are put in about every 6 sets or so, depending on the nature of he ground; lagging is often 9 ins. × 3 ins. plank.

Round Shafts.

Round shafts are lined with brick or concrete in ordinary strata; special methods are adopted here shaft traverses water-bearing strata and the lining is required to keep back water. For afts over 18 ft. in diameter ordinary brick may be used; for smaller shafts wedge bricks should e employed. Let f be the width of the inner face of the brick, b of the outer face, l the length f the brick and R the radius of the shaft. Then $b = \frac{(R + l\,f}{R}$; if, as is often the case, $l = 2f$, is becomes $b = f + \frac{2\,f^2}{R}$. Instead of bricks, firebrick lumps 6 ins. × 8 ins. × 12 ins. to 8 ins. ×) ins. × 15 ins. may be used. They should also be made wedge shaped in accordance with the ove formula. A shaft 10 ft. in diameter lined one brick thick requires about 350 bricks laid mortar, per foot of depth. The thickness of the lining depends on the nature of the ground nd the diameter of the shaft.

Cost of Sinking.

The cost of sinking may be taken as made up of five main items: Supervision, labour, materials, ower, and interest on capital expended.

Sinking in ordinary coal measures costs 1*l.* to 2*l.* per fathom for each foot in diameter of ie shaft; to this must be added surface labour, fuel, etc., 30*l.* to 50*l.* per week. If more ater than 100 gallons per minute is met with, these costs will increase rapidly. Walling, cluding the cost of the bricks, amounts to between 15*s.* and 30*s.* per cubic yard of brickwork. 'alling a shaft 13 ft. in the clear, 15 ft. over all, cost about 15*l.* per fathom = 30*s.* per cubic ard; walling a shaft 22 ft. in the clear, 25 ft. over all, cost 24*l.* 5*s.* per fathom = 15*s.* 6*d.* er cubic yard. A walling curb costs about 10*l.* Sinking a shaft 12 ft. in the clear cost 24*l.* per thom (sinkers and waiters-on, 13*l.* 10*s.*; general labour, 7*l.* 10*s.*; explosives and stores, 3*l.*). inking a shaft 13 ft. in the clear costs 23*l.* to 30*l.* for labour in ordinary strata, and 70*l.* to 00*l.* in basalt, per fathom.

Sinking two shafts at Hylton colliery in 1897–99 cost as follows per fathom:—

	Shaft 20 ft. in the clear.						Shaft 15 ft. in the clear.					
	£	*s.*	*d.*	£	*s.*	*d.*	£	*s.*	*d.*	£	*s.*	*d.*
Labour—Sinkers (incl. explosives)	21	0	6				17	0	0			
Wallers	7	7	2				5	11	0			
Miscellaneous	8	7	4				2	16	0			
				36	15	0				25	7	0
Materials—Bricks	9	12	0				5	2	0			
Cement, lime, sand	4	16	0				2	11	0			
Walling cribs	2	6	0				2	0	0			
Miscellaneous	0	15	0				0	10	0			
				17	9	0				10	3	0
Total per fathom				54	4	0				35	10	0

Sinking three 20 ft. shafts at Horden, each 210 fathoms deep, against a flow of 9,000 gallons water per minute, cost 350,000*l.* (*J. J. Prest.*)

The cost of sinking and tubbing a section of 22-ft. shaft at Blackhall with feeders of wate from 300 to 2,885 gallons per minute was as follows :—

	£	s.	d.	
Underground labour	70	10	10	per linear yard.
Surface „	26	13	7	
Materials, coal and stores	87	2	1	
	£184	6	6	

The cost of sinking a 22-ft. shaft through limestone and tubbing it, against feeders of wate averaging 3,000 gallons p.m., may be averaged at about 275*l.* per yard of depth.
(*J. J. Prest*, Tr. Inst. M. E. xlvii. p. 611.)

Shafts may be lined with cement, either by setting sheet iron cylinders and ramming concret round these, lifting the cylinders when the cement has set, or by walling with thin blocks or slat (about 2 ft. 6 ins. × 3 ft. 6 ins. × 5 ins.), and ramming cement behind this facing ring. Th cost of an 18-in. monolithic lining in a 22-ft. finished shaft was made up as follows :—

	s.	d.	
Mixing concrete	1	0	per cub. yd.
Cement	4	2	„
Lining shaft with concrete	2	6	„
Coal and stores	0	9	„
Steel cylinders and other plant	1	4	„
Total	9	9	per cub. yd.

There were 28 cubic yards to the fathom, hence the cost per fathom was 13*l.* 13*s.* It took seve hours to complete the concreting of one fathom.
The cost of walling a similar pit with brickwork was 24*l.* 3*s.* 3*d.*
Lining a 22 ft. shaft at Blackhall with a monolithic cement concrete (6 : 1) lining cost pe linear yard :—

	£	s.	d.
Labour in loading sand and gravel	1	18	6
Enginemen and attending mixer	0	4	1
Cement	3	13	6
Interest and depreciation on shuttering, etc.	0	19	0
Coal, stores, etc.	0	10	6
Labour in shaft	3	1	7
	£10	7	2

Lining with concrete blocks 3 ft. 6 ins. × 2 ft. 6 ins. × 5 ins. backed solid by ramming l concrete, all also 6 : 1, cost practically the same. The average cost of sinking and walling wit 18 in. concrete was 26*l.* 1*s.* 8*d.* inclusive. Suitable bricks would have cost 45*s.* per 1,000, an at this price brickwork in cement would have cost 15*l.* per running yard. (*Loc. cit.*)

In a 14 ft. pit the total costs of labour for sinking and concreting came to 15*l.* 15*s.* per fathom The cost of the concrete was about 21*s.*, and the labour of lining the shaft with it about 1*s.* 6*d* or altogether 22*s.* 6*d.* per cubic yard. There were 10½ cubic yards per fathom, so that the cos of the concrete lining amounted to 11*l.* 16*s.* per fathom; with four men at the surface and fou men in the pit, the concrete was put in at the rate of a fathom in six hours. At Karwin, Silesi an 18 ft. shaft was lined with concrete put in from above downwards at the rate of a fathom i fourteen hours at a cost of 62*l.* per fathom complete; the same shaft lined in the upper part wit brickwork had previously cost 132*l.* per fathom. Ferro-concrete has been used in place of simpl concrete. At Zweckel, near Gladbeck, a shaft was lined with ferro-concrete slabs backed wit concrete, into which the iron framework of the slabs was continued, for 23*l.* per fathom. A Rheinelbe a shaft 20 ft. in diameter was lined with Monier ferro-concrete 11 ins. thick at a cos of 2*l.* 5*s.* 6*d.* per cubic metre of lining, or 30*l.* 12*s.* per fathom of shaft: for a similar shaft at th Hansa Colliery lined 9½ ins. thick the prices were 2*l.* 3*s.* 6*d.* per cubic yard or 29*l.* 14*s.* per fathom.

Shaft Lining.

In heavily watered strata a lining has to be put in strong enough to resist the pressure of water. The thickness of such lining may be calculated as follows :—

Let R be the internal radius of the shaft, *s* the maximum admissible stress in the wall, *p* th pressure to be resisted, all to the same units, which are preferably inches and pounds, then :—

$$\text{Thickness of wall} = R\left(\sqrt{\frac{s}{s-2p}}-1\right)$$

(*Aldis*, N.E. Inst. M. E. xxxii. p. 201.)

The resistance to crushing of the various materials used in lining shafts is :—

Common brick	800 to 1,000 lbs. per square inch.
Fire brick	1,500 to 2,000 " " "
Sandstone	2,000 to 5,000 " " "
Concrete 1 : 3 : 6 to 1 : 1 : 3.	1,500 to 5,000 " " "
Average	3,000 " " "
Cast iron	90,000 to 120,000 " " "

Safe loads may be taken as $\frac{1}{10}$ of these; for best brick laid in 1 : 3 Portland cement up to 50 lbs.; for ferro-concrete up to 600 lbs. per sq. in.; for frozen sand fully saturated with water at −12° C. up to 340 lbs. per sq. in. (*Alby*, Bull. Soc. Ind. Min. 1895, p. 273.) L. Sauvestre has shown that frozen sand is highly plastic, and that its resistance to crushing increases by 8½ lbs. per sq. in. for each drop of 1° C. (*Annales des Mines*, Ser. xi., vol. ix., 1920, Pt. I, p. 5.)

The pressure to be resisted is usually taken merely as the head of water—namely, 0·434 h lbs. per sq. in., where h is the head expressed in feet. For quicksands Poetsch adopts a formula equivalent to $p = 1{\cdot}042\ h \tan^2\left(45° - \frac{\alpha}{2}\right)$, where α is the angle of repose of the sand; Poetsch gives $\alpha = 35°$ for fine quicksand, and 20° for coarse sand. These figures are used in calculating the thickness of the ice-wall required in the freezing method of sinking.

Many approximations are used for ordinary shaft linings :—

J. J. Atkinson : Thickness in inches $T = \frac{5{\cdot}2\ R\ h}{s - 0{\cdot}434\ h}$, or for cast iron $T = \frac{5{\cdot}2\ R\ h}{9{,}000 - 0{\cdot}434\ h}$.

Chaudron: for cast iron, $T = 0{\cdot}8 + \frac{0{\cdot}434\ R\ h}{600}$ where $h < 165$ ft. and $T = \frac{130}{h} + \frac{0{\cdot}434\ R\ h}{600}$ where $h > 165$ ft. (here s is taken at only 7,200).

Riemer takes $s = 11{,}400$, and writes :—

$$T = 0{\cdot}8 + \frac{0{\cdot}434\ R\ h}{950} \text{ for } h < 165,$$

$$\text{and } T = \frac{130}{h} + \frac{0{\cdot}434\ R\ h}{950} \text{ for } h > 165.$$

Cast-iron tubbing is always stiffened by ribs and flanges, and these should be taken into account (see *Morrow*, Trans. Inst. M.E. xxxiv. p. 100).

Coffering.

Coffering may be used for moderate pressures and shallow depths; costs range from 20*l.* 10*s.* per fathom (16-foot shaft) to 38*l.* per fathom (18-foot shaft), being considerably less than cost of cast-iron tubbing.

Tubbing.

Tubbing is put in either by English or German method: in the former, segments are 2 ft. to 3 ft. deep, flanges are external, not machined, and the joints are made with wood sheeting and wedges; in the latter, segments are 5 ft. to 6 ft. deep, flanges are internal, are machined, and the joints are made with lead sheeting and bolts. In both forms the tubbing is carried upon wedging curbs, followed usually by a foundation ring. In some few recent cases the wedging curb has been dispensed with, and the tubbing set direct upon a good bed.

Cost of Tubbing.

Cost of English tubbing varies with the price of pig iron, etc., from 5*l.* to 7*l.* 10*s.* per ton; cutting in the tubbing costs 2*l.* to 2*l.* 10*s.* per ton of tubbing put in, or 5*l.* to 7*l.* per fathom of shaft. The following are the detailed costs of tubbing a 15 ft. shaft with 12 segments to the ring, 2 ft. deep, ¾ in. thick, each ring weighing 2 tons 10 cwt.:—

	£	*s.*	*d.*
Three rings, 7 tons 10 cwt. at 7*l.* 10*s.*	56	5	0
Sheeting, 213 ft. at 8*s.* per 100	0	17	0
Wedges, 3,500 at 10*s.* per 1,000	1	15	0
Labour, putting in and wedging	6	0	0
Total	64	17	0
Cost per fathom, about	64	0	0

To the above must be added a due proportion of the wedging curb. The castings for the curb of a 15-ft. shaft cost 25*l.* to 35*l.*, sheeting and wedges 5*l.*, putting in and wedging 10*l.* to 15*l.* Dressing the curb seat may cost from 10*l.* to 40*l.* according to circumstances. About ten men are usually employed in the shaft in wedging tubbing, and they can wedge two to three rings per shift.

The cost of 'German' tubbing usually comes out a little less than English tubbing per fathom. The seams and joints are all machined, this costing 3*l.* 10*s.* to 4*l.* per ring; three shifts of four men can put in and bolt up four rings (20 to 24 ft.) per 24 hours.

The cost of 'German' tubbing in an 18-ft. shaft, the tubbing being 1 in. to 1¼ in. thick, 12 segments to the ring 5 ft. deep, was as follows in this country :—

	£	*s.*	*d.*	
Cast-iron tubbing, 13 tons 4 cwt. at 7*l.* 10*s.*	99	0	0	per fathom
Lead for sheeting and washers, 6 cwt.	6	0	0	
Bolts and nuts	3	5	0	
Labour	7	10	0	
Cost per fathom	115	15	0	

In the Minister Achenbach Colliery a shaft 17 ft. in diameter was tubbed with 18 rings of tubbing 8 ft. 2 ins. high, 1 in. to 1¼ in. thick, each ring composed of 10 segments. The weight of material employed were :—

Tubbing	192 tons 10 cwt.	Lead washers	1 ton 2 cwt.
Lead strips	2 „ 8 „	Bolts, nuts and washers	6 „ 3 „

Where the ground is weak and apt to run, suspended tubbing can be used to much advantage. This method was used at Astley Green (*Trans. Inst. M. E.* xxxix. p. 543), also at Hamsterley (*Trans. Inst. M. E.* xxxviii. p. 320); the latter shaft was 10 ft. in diameter and 35 ft. deep. The cost was :—

Materials, 627*l.* 2*s.* 10*d.*, labour, 141*l.* 0*s.* 3*d.*, equal to 83*l.* 16*s.* per fathom. The method is to be recommended for safety, speed and economy.

The above, which may be called ordinary methods of sinking, can only be used where a moderate influx of water has to be contended with; the greatest quantity ever dealt with by these means has been in the sinkings at Blackhall Rocks, where the Horden Colliery Company has sunk two shafts through the Magnesian Limestone in which 14,300 gallons per minute were being pumped from a depth of about 90 yards. Very much less than this is generally sufficient to cause special methods to be resorted to, 5,000 gallons per minute being generally considered prohibitive. The increase of cost due to a heavy flow of water in deep sinkings is well shown by a table of estimated costs of sinking in wet ground in Westphalia :—

COSTS OF SINKING SHAFTS 16 TO 17 FT. IN DIAMETER IN WESTPHALIA PER FATHOM.

To Depth of	Where the Average Flow of Water is	
	880 Gallons per Minute.	1,760 Gallons per Minute.
Fathoms.	£	£
27	458	548
55	566	750
82	686	960
110	804	1,170
137	914	1,316
164	1,006	1,554
219	1,188	1,920
273	1,316	2,286
328	1,554	2,652

(*L. Hoffman*, 'Glückauf,' xxxvii. p. 775.)

COST OF SHAFT SINKING IN GOLD MINES.

A shaft 4 ft. by 8 ft. in clear can be sunk in California, where wages are 14*s.* per shift, by hand drilling, at a cost of 4*l.* 10*s.* per foot. This includes labour, timbering, explosives and supplies. The hoisting done by a horse whim and no water to pump. The rate of progress is about one foot per day.

In Nevada a shaft 4 ft. by 8 ft. in clear was sunk 100 ft. in 31½ days by means of hand drilling. The cost per foot was 6*l.* 10*s.* Labour 16*s.* per shift.

Large Shafts.—In Western Australia shafts vary from 4 ft. by 10 ft. to 5½ ft. by 13½ ft. On eleven of the mines in the district the cost per foot of shaft is from 11*l.* to 16*l.*, and from 2*s.* 9*d.* to 5*s.* 6*d.* per cub. foot of material excavated. The average monthly advance was 34 ft. to 60 ft. with an average of 50 ft. Machine drills used on all above shafts.

In Utah, wages 12*s.*, a shaft 17 ft. by 65 ft. was sunk in ground of medium hardness at a ost of 12*l.* per foot driven or 1*l.* 16*s.* per ton of material broken. Machine drills used. Pumping om 300 ft. Rate of sinking 0·9 ft. per day.

On the Rand a shaft (Brakpan, Ltd.) 43 ft. by 9 ft. in the clear was sunk at a rate of 204 ft. er month. The working cost was 14*l.* 10*s.* per foot and the total cost 22*l.* 14*s.* per foot. Ground oft. Hand drilling employed.

The following are some of the Rand shafts and the cost per ton of material handled :—

Shaft.	Size.	Speed per Month.	Cost per Ton.	Method Employed.
			s. *d.*	
Rand Collieries . .	34 ft. by 9 ft.	120 ft.	10 9	Machine
Kleinfontein . .	34 ft. by 9 ft.	107 ft.	11 8	,,
Brakpan . . .	43 ft. by 9 ft.	124 ft.	8 11	Hand.
City Reef . . .	46 ft. by 9 ft.	125 ft. 6 ins.	9 2	,,
Hercules . . .	47 ft. by 9 ft.	119 ft.	8 5	,,
Wolhunter . . .	46 ft. by 9 ft.	95 ft.	10 6	,,

The Inspiration Copper Company, Miami, Arizona, sunk and completed a shaft 12 ft. 4 in. by 6 ft. 8 in., 1,400 ft. deep in 10 months.

Some exceptionally fast sinking has been done on the Rand ; thus, in one of the shafts on the rown Mines 318 ft. were sunk in August, 1925, and in one on the Randfontein Estates 386 ft. ere sunk in June 1926.

Ferro-concrete Tubbing.

(The François Cementation Co., Ltd.)

Ferro-concrete tubbing of monolithic construction is rapidly supplanting cast-iron tubbing s shaft lining. As compared with cast-iron tubbing the cost is, roughly, the same for the first 5 yds. in depth, but thereafter it becomes relatively very much cheaper. Other advantages re that it does not corrode, does not require wedging, repairing, or renewing, but increases in trength with age ; with great inertia it has great flexibility ; it is not appreciably affected by emperature variations, and it is easily adaptable to change of size while sinking. The cost of erro-concrete tubbing, to resist a static pressure of 250 lbs. to the sq. in., with a safety factor f 2 for an 18-ft. diameter shaft, is calculated at 65*l.* per lineal yard.

Winzing and Raising.

At Park City, Utah, winzes 11 ft. by 7·5 ft. in quartzite are sunk at a cost of 6*l.* per foot ink, or 1*l.* 10*s.* per ton of material broken. The advance is about 1 ft. per day. In same mine aises, 17·5 ft. by 5·5 ft., are put up at a cost of 1*l.* 14*s.* per foot or 4*s.* per ton of materia broken. he advance is at the rate of 3·3 ft. per day.

In Western Australia winzes are from 4 to 5 ft. in width and 6 to 8 ft. long. They are 50 ft. o 200 ft. deep, and the average total cost per foot in eleven of the mines is 4*l.* 15*s.*

The rises in the same district extend from 25 ft. to 120 ft. in height, and are 4 ft. to 5 ft. wide nd 6 ft. to 8 ft. long. The total cost on the average is 3*l.* 18*s.* 7*d.* per foot.

Special Methods of Sinking.

In hard, very wet ground :—

Kind-Chaudron : maximum diameter of shaft, 15 ft. ; greatest depth yet attained by it, 335 ft. ; Nos. 1 and 2 pits Marsden Colliery (the first sunk in this country by this method) ost respectively 362*l.* 8*s.* and 293*l.* per fathom ; in the North of France shafts 8 to 12 ft. iameter to depth of 100 fathoms cost 80*l.* to 240*l.* per fathom, and the rate of sinking varied om 2 to 6 fathoms per month. In Germany it is estimated that to sink 55 fathoms by this rocess at a depth of about 300 fathoms would cost about 1,400*l.* per fathom for a shaft ft. 6 ins. in diameter.

Poetsch Freezing Process.—Applicable both to fissured firm ground and to running ground he brine used is a 25 per cent. solution of magnesium chloride cooled down to —20°C., its freezing oint being about —35°C. The following table shows the pressures at which ammonia gas quefies at different temperatures :—

Temperatures.		Pressures in Lbs. per Sq. In.
—20°C.	— 4°F.	27
—10°C.	+14°F.	41
0°C.	+32°F.	62
+10°C.	+50°F.	89
+20°C.	+68°F.	125

It is estimated that to produce 100,000 negative calories per hour at —15° C., 50-60 h.p. are required at the freezing plant, and that 0·25 lb. of ammonia and 2 gallons of brine are required for each yard in length of the freezing circuit.

Saturated sand (165 parts water to 1,000 parts sand) frozen at 32° F. has a crushing strength of 242–341 lbs. per sq. in., and at — 13° F. of 2,845 lbs. per sq. in.

Shafts have been sunk to 130 fathoms by this method, the cost for shafts 13 ft. to 16 ft. in diameter ranging from about 150*l.* to 250*l.* per fathom. The cost of sinking two pits, 12 ft. and 16 ft. 6 ins. respectively in diameter, at Anzin, in 1895, to a depth of 50 fathoms, was as follows :—

	£	s.	d.	£	s.	d.
Cost of freezing plant				73	2	0
Cost of freezing operations				48	6	0
Cost of sinking and tubbing : labour	32	16	0			
Cost of tubbing	66	10	0			
				99	6	0
Total cost per fathom				220	14	0

The cost of sinking a pair of 20 ft. shafts by freezing under ordinary conditions should be :—

	£
To a depth of 50 fathoms	17,500
" " 100 "	28,000
" " 200 "	50,000

(*W. W. Wilson*, Tr. Inst. M.E. xli. 353.)

Freezing an 18-ft. shaft at Monkwearmouth cost 230*l.* per fathom to a depth of 60 fathoms.

A deep sinking was carried out by this process at Beeringen in 1920 ; a depth of 1,640 ft. of clay, quicksand, and water-bearing chalk was first sunk through in this way, and subsequently the process was applied to the more difficult task of passing through a bed of running sand 46 ft. thick, at a depth of 2,000 ft. under a pressure of 926 lbs. to the sq. in.

(*Annales des Mines*, Ser. xi., vol. ix., 1920, Pt. I. p. 5.)

At Seaham, Co. Durham, there are three freezing units, one of 300,000 negative calories and two of 150,000 negative calories each per hour (300 and 150 h.p. respectively). There are five double-acting brine pumps 10 in. diam., 10-in. stroke ; the brine is calcium chloride solution of sp. gr. 1·25. Two shafts are to be sunk 21 ft. diam. in the clear to a depth of about 490 ft.

Cement Injections.—This has been used with success in several cases, first by M. Reumaux at Lens, by M. Deffieux at the Mine de Marles (1908), and by M. François in this country ; in the former case the cost was about the same as that of freezing. The François system consists in boring 10 to 20 holes within the shaft, the bottom being first, if necessary, sealed with a plug of cement concrete ; cement slurry is forced through these holes at pressures up to 500 lbs. per sq. in., so as to fill all fissures when sinking is resumed ; another section is then cemented, and so on. Cementation in ordinary ground will cost about 50*l.* per yard for a 20-ft. shaft. See paper, Trans. Inst. M.E., liii. (1916–17), p. 22.

This system has been used in sinking a shaft 16 ft. in diameter at the Holditch Iron Mine, Chesterton, Staffs. The shaft is sunk through the water-bearing Keele strata to a depth of 632 ft., the upper bed giving off 30,000 gallons of water per hour. The total time occupied was 69 weeks, and the costs were 40*l.* 4*s.* 4*d.* for labour and 36*l.* 3*s.* 9*d.* for material per yard of finished shaft (1916–17), or together 76*l.* 8*s.* 1*d.* ; it is estimated that sinking with underhung tubbing would have cost 91*l.* 4*s.* 8*d.* The shaft was lined with reinforced concrete. Cement for injection of boreholes 350 tons 13 cwt., for the concrete walling 998 tons 6 cwt., and for the injection of the walling 50 tons 10 cwt. (*A. Hassam and T. T. Mawson*, Trans. Inst. M.E. lviii. p. 16.)

In porous sandstones M. François first injects separately solutions of silicate of soda and sulphate of alumina, and follows this up with cement. This process was used successfully at Hatfield Main, Thorne, etc. Two shafts were sunk successfully at Ollerton by this process.

In the sinking of No. 19 pit at Courrières in 1909, which was sunk by the freezing method, difficulties were encountered in the upper part of the shaft owing to running water, and these were overcome by the injection of cement to a depth of 57 ft. ; over 1,000 tons of cement were used. (*Annales des Mines*, Ser. xi., vol. ix., 1920, Pt. I. p. 38.)

In sinking through strata containing brine, *e.g.* in certain potash mines, the temperature must be reduced below —35° C. Liquid carbonic acid must be used instead of ammonia in the freezing plant and calcium chloride brine. (*Glückauf*, vol. 63, 1927, p. 293.)

In running ground :—

The Sonnenschein cementation process for sinking through quicksands consists in boring a number of holes about 5 m. deep, relatively close together, through the concrete plug in the shaft bottom. When a sufficient number of holes have been bored, water is forced down a borehole adjoining the one to be treated, thus forcing the quicksand up the latter, and leaving a conical cavity in the quicksand below the plug. Cement slurry is then forced down the borehole to be treated until the cavity previously formed is filled with cement, and the operation is repeated until a continuous body of cement, about 5 m. deep, is formed below the plug. The cement is then excavated until only enough is left to form a fresh plug, and the entire operation is repeated until the quicksand has been traversed.

THE

FRANÇOIS CEMENTATION PROCESS

is sure and safe, efficient and economical, and has the benefit of wide and successful experience.

To Mining Engineers.

We can save you money and help you with difficult problems due to Presence of Water or Bad Ground.

Sinking Shafts; Driving Drifts or Tunnels; Building Dams; Sealing off Leakages in Shafts, Lodge Rooms, Tunnels or Roadways; Injecting Faulty Tubbing; Installing Ferro-Concrete Lining; Repairing and Re-Lining Old Furnace Shafts; Reclaiming Flooded Mines; Installing Shaft Plugs; Quenching Gob Fires; Diamond Drilling, Strengthening and Repairing Foundations, etc., etc.

F. 2579

Sheet piling can be used for relatively shallow sinking, near the surface. At Bowburn Colliery Co., Durham, 6 fathoms of wet sand were driven through by wooden piles in 1906 at a cost of 26*l.* per fathom for timber and 34*l.* 10*s.* for labour. Interlocking steel piling (p. 607) of joists of various forms has also been used.

The dropshaft method is employed in various forms, sometimes by weighting a cutting shoe and curb, on which an iron or brickwork cylinder is built up, or more usually by building a brick or concrete pressure block against which work hydraulic rams that force down tubbing of cast iron, or in exceptionally difficult cases of cast steel. The former method (forcing down a shoe by dead-weight) was found much superior to forcing a shoe down by jacks in sinking a shaft 14 ft. by 8 ft. through 70 ft. of loose strata at Des Moines, Iowa (*Trans. Amer. Inst. Min. Eng.*, vol. lv., p. 232). The following table shows probable costs for shafts of normal size in ordinary running ground (Hoffman):—

For depth.	Cost per fathom sunk.	For depth.	Cost per fathom sunk.
	£		£
From 15 fathoms to 27 fathoms .	320	From 82 fathoms to 110 fathoms .	1,280
„ 27 „ to 55 „ .	732	„ 110 „ to 137 „ .	1,554
„ 55 „ to 82 „	1,006	„ 137 „ to 165 „ .	1,830

The *Honigmann* system has been used in a few cases down to depths of 70 fathoms on the Continent; the shaft is bored out by a dredge-borer, the walls being kept up by internal hydrostatic pressure, and the shaft is lined with tubbing composed of rings of channel iron riveted together and subsequently lined with concrete.

A sinking with a timber drop shaft lining is described in the February, 1922, *Bulletin of the Canadian Institute of Mining and Metallurgy*.

The François Cementation Process.

The origin of the use of cement grout in mine shafts is not certain. Probably the first fully authenticated use was in the injection behind shaft lining at the Rheinpreussen shaft, near Homberg, in 1864, at a pressure of 210 lbs. to the square inch. Monsieur H. Portier at Courrières in 1900 successfully injected and sealed a considerable feeder of water behind an old shaft lining of wood. Cement injection was successfully employed at a shaft sinking in Germany by R. A. Weide, at Pohlhauer, Saxe, in 1901. Early examples of its use in France were by Monsieur Remaux at Lens; and by Monsieur Deffieux at the Mine de Marles in 1908. In 1911 Mr. Albert J. François, who had previously spent some years on the Continent in experimenting with various systems of cement injection behind shaft lining and through various classes of strata, introduced his process in England, where its possibilities were at once recognised by colliery engineers, and where Mr. François was given every opportunity to improve his patents and develop his process. Over the previous crude systems his methods were as distinctive and advanced as their success was marked, and his process proved a valuable aid to the development and maintenance of coal mines in wet areas.

The process has since been introduced into France, Belgium, Germany, and South Africa, where it is extensively used. In all, forty shafts have been sunk by its means. The preliminary silicatisation of the ground, which is an essential part of the process, was first tried at Hatfield Main, in 1911, with complete success. In porous or finely fissured strata, or alluvial deposits, or generally where the injection of cement slurry proves difficult, the preliminary preparation of the ground by the injection of solutions of silicate of soda and sulphate of alumina is used, the shaft is sunk by ordinary methods until the presence of water is indicated by means of test holes. A number of holes are then bored in the shaft bottom, pipes being cemented in them, their number, position, and inclination being dependent upon the size of the shaft and the character of the strata. Through these pipes boreholes are sunk by means of a diamond drill. On the tapping of feeders by one of the holes the boring is immediately stopped and the pipe in the hole connected by means of a length of high pressure flexible hose to a column of pipes in the shaft, leading in turn to a cement pump and mixing tank on the surface. The holes are arranged in series for cementation and silicatisation, and into them cement pulp and mixtures of chemicals are pumped, the strength and proportion of the mixtures of chemicals, the percentage of cement, and the pressure employed being such as experience has shown to be best suited to the class of strata and pressure of water to be treated. The holes are cleaned out and reinjected or further deepened as necessary, the process being repeated with the various holes, boring and injecting of the different holes taking place simultaneously. The ground is treated in this manner until the desired length of ground has been rendered sufficiently watertight to allow mining and walling operations to proceed. The ground is excavated in the ordinary manner and reinforced concrete walling built up, any water not sealed off by the cementation of the boreholes being shut off by injections between the completed lining and the ground. On the walling being completed a second length of ground is excavated and walled, this procedure being continued till the water-bearing strata has been passed through. The lining employed through water-bearing or bad ground is ferro-concrete tubbing of monolithic construction. Cementation in ordinary ground will cost about 50*l.* per yard for a 20-ft. shaft (see *Transactions of Mining Engineers*, vol. liii., 1916, p. 22). For a more complete description of the process see paper by H. Standish Ball, *Proceedings of South Wales Institute of Engineers*, vol. xxxvi. No. 2, p. 111. See also p. 2578.

Mr. Eustace Mitton estimates the cost of sinking through the Bunter sandstone by cementation, including the installation of ferro-concrete tubbing to a depth of 200 yards for an 18-f shaft, at £350 per lineal yard. (*Midland Counties Institute of Engineers*, October 15, 1921.)

At two shafts recently completed at Harworth Main, where there was an indicated quantit of water of 3,000 gallons per minute, the shafts were rapidly and successfully sunk by th François process, with a total residual water in both shafts of 6 gallons per minute (see 'Harwort Sinkings,' *Colliery Guardian*, Nov. 17, 1922; see also p. 2578); while at two shafts recently com pleted at Ollerton Colliery, where the estimated amount of water was even greater than this, th shafts were sunk by the François process with an average of residual water of only two gallo per minute in each shaft. (See paper read by Mr. H. Eustace Mitton before the Institution Mining Engineers, November 4, 1925.)

The François cementation process was successfully employed in preference to sheet pili at Haugh Colliery, Kilsyth, Scotland, for sinking from the surface to some 6 fathoms in dept through running ground.

See also L. Souvestrie, *Annales des Mines*, 12th series; *Colliery Guardian*, Nov. 10, 192 an article in the *Iron and Coal Trades Review*, Sept. 8, 1922; *Kropf Industriebau*, Oct. 15, 192 'Cementation des Grès Vosgiens,' by F. Arguillère, *Rev. Ind. Min.*, Nov. 1, 1927, p. 451.

The time required to cement a 20-yd. length of shaft in various rocks is as follows:

Bunter Sandstone	16 days	Limestone	18–19 days
Pennant Sandstone	16 ,,	Chalk	12 ,,

and the quantity of cement required per yard of 20–22 ft. shaft has been found to be:—

Pennant Sandstone	15 cwt.–3 tons	Bunter Sandstone	5 tons–6 ton
Magnesian Limestone	2 tons–4 tons	Chalk	up to 4 ton
Triassic Sandstone	3 tons–6 tons		

Where silicatisation is employed, the consumption of silicate of soda is 1½ to 5 tons per line yd., and that of sulphate of alumina about half of this.
(*Vertical Shaft Sinking*, by E. O. Forster Brown, 1927, pp. 147, 148.)

Under special conditions when very rapid setting cement is required, 'cement fondu' h been used in place of ordinary Portland cement, and in intensely cold ground a mixture magnesia and magnesic chloride has been used.

List of Deep Shafts in the World (1912).

Rosebridge	Lancashire	2,446	Coal

The Barnsley Bed was cut in the Thorne sinkings at 2,765 ft. on August 22, 1924.

In 1924 the total depth of all shafts in mines in Great Britain coming under the C.M.R. Act was 45,000 yds, and the ratio of shaft yardage to average tons of daily output was 1 : 1·183 ; in the U.S.A. the ratio of output appears to be at least 15 times as great.

(*Vertical Shaft Sinking*, by E. O. Forster Brown, 1927, p. 372.)

Coal Cutters.

In coal-getting by longwall, props with lids are set along the working face at definite distances apart, there being 1, 2, or 3 rows, as conditions may require. As far as possible, these props are drawn as the face advances, the control of the roof being a matter of prime importance. Steel props, constructed so as to yield to some extent under pressure, have been substituted with much advantage in several places. In the U.S.A. some collieries have adopted adjustable chocks, which can be advanced by screw or hydraulic jacks.

In hand kirving, the average height of a kirving is 13½ ins. in front and 1⅜ in. at back, by a depth of 3 ft., giving a volume of 1·9 cub. ft. of coal kirved out per linear foot of coal face (equal to 16 per cent. on a 4 ft. seam). In a 6-hour shift a hewer in ordinary coal will kirve a bord 5 yds. wide to a depth of 1 yd. or about 7½ sq. ft. per hour of shift. A man will kirve about 9 sq. ft. per hour's actual hewing time after the jud has been nicked in a bord ; in a wall he can kirve about three-quarters as much as in a bord, and in longwall work he can kirve one and a-half times as much as in average narrow work. Allowing for his other work a hewer in Northumberland and Durham averages about 38 sq. ft. of kirving per shift.

Machine cutting gives up to about 65 per cent. more output per man employed ; on the average about 10 per cent. more round coal is made by machine than by hand ,and a greater output of coal can be obtained from a given seam.

Coal-cutting machines for longwall work are chain-cutters, disc-cutters and bar-cutters, the former being applicable in seams where the coal is fairly hard, the cleat not too well marked, and the roof tolerably good. The disc machine makes a kirving 3⅜ ins. to 5½ ins. deep, the bar machine a kirving tapering from 7½ ins. in front to about 3½ ins. at the back. Machines may be air-driven, using compressed air at 35 to 65 lbs. per sq. in. at the machine, or electrically driven (direct, alternating, or tri-phase) at voltages of 250 to 450. The power consumption varies between wide limits, between 12 and 30 h.p. Compressed air coal-cutters cost 250*l*. to 300*l*., electrically-driven coal-cutters 350*l*. to 450*l*. ; a complete plant for a pit using 10 machines would cost about 10,000*l*. with the former and 11,000*l*. with the latter form. The area undercut per hour varies from 45 to 140 sq. ft., 90 sq. ft. being about an average, per hour of running time. An average shift's work may be taken as about 500 sq. ft. Air consumption 1,000 to 3,000 cub. ft. free air per sq. yd. undercut.

According to Mr. Mavor (*Trans. Inst. Min. Eng.*, vol. l., p. 641) a good compressor will compress 6 cub. ft. free air per minute to 60 lbs. per sq. in. per b.h.p. Tests showed coal cutters to use 143 to 1,146 cub. ft. free air per minute, or 620 to 3,642 cub. ft. per sq. yd., at mean pressure of 23 lbs. per sq. in. at machine and 68 lbs. at compressor.

Costs.

Mr. Mavor gives average costs as follows :—

	Per shift. s. d.	Per ton. d.
Interest 5 per cent. on 450*l*.	1 9	0·21
Depreciation 12½ per cent.	4 4	0·52
Labour	33 0	4·00
Air power	23 0	2·77
Picks, oil, etc.	8 4	1·00
Repairs	12 10	1·50
Total	83 3	10·00

Gate-end loaders are coming into use.

In narrow work percussive coal-cutters are mostly used, also chain-heading machines and arc wall machines. Percussive cutters supported on a fixed column are mostly in favour ; they work with compressed air at 50 to 70 lbs. per sq. in., the air consumption being 100 to 300 cu. ft. of compressed air per sq. yd. undercut ; different makes run at 300 to 600 blows per minute. A machine has undercut 30 sq. ft. per hour, but their usual performance is 80 to 100 sq. ft. per shift. Percussive cutters of the Ingersoll type on wheels are also used ; these machines weigh 5 to 7½ cwts. ; they use air at 70 to 90 lbs. pressure per sq in., with an average consumption of 100 cu. ft. of free air per min., and strike about 150 blows per min. ; they will undercut 15 to 50 sq. ft. per hour of running time, or 50 to 200 sq. ft. per shift.

Chain heading machines may be driven electrically or by compressed air, using 10 to 20 h.p. ; these machines can undercut about 50 sq. ft. per hour, but it is rare that 200 sq. ft. can be kirved per shift. See 'The Driving of Narrow Places,' by S. Walton-Brown (*Trans. Inst., M.E.*, vol. lxxiii, 1927, p. 506).

Arcwall machines will cut 10 to 15 places per shift in roads 4 to 5 ft. wide, the usual depth of undercut being about 6 ft. ; these machines weigh about 3½ tons, and their motors develop about 40 h.p.

The Stanley header cuts roads circular in cross-section through coal, using 15 to 40 i.h.p. road 5½ ft. in diameter can be driven through coal at the rate of 10 ft. per 8-hour shift, or six time as fast as handwork, the cost being sometimes rather less, sometimes rather more than han labour, namely 2*s*. 6*d*. to 4*s*. per foot of advance, everything included, as against 2*s*.8*d*. per hand.

The Jeffrey Entry driver cuts, breaks down, and loads the coal into tubs.

In the U.S.A. Longwall machines with jibs 40 ft. long cut and load 350 tons per shift. machine with a 50 ft. jib is worked by five men, and in a 6 ft. seam with a strong sandstone ro cuts and loads 200 tons per shift or 400 tons per day ; a machine with a 200 ft. jib, to cut and loa 1,000 tons per shift. is being built.

In connection with coal-cutters in thin seams face conveyors are much used for bringing th coal to the gateways. There are four main types :—(1) troughs containing scraper-chains, eithe endless or reciprocating, (2) endless belts, (3) shallow trucks or trays hauled by ropes, (4) shak conveyors. The Blackett conveyor is an example of the first type ; the chain is 6-inch pitch an rests in a trough 12 ins. wide at the bottom, 18 ins. at the top, 9 ins. deep, made in 6 ft. lengths ; will carry up to 30 tons per hour along faces 100 yds. in length. Most of the other forms hav lower capacities. and are suited to smaller outputs or shorter faces. In one case where hand-cuttin and filling cost 2*s*. 4*d*. per ton (face costs only), machine cutting and hand filling cost about 1*s*. 8 per ton (1*s*. 4*d*. face costs, plus 4*d*. for power, repairs, stores, depreciation), and machine cuttin and conveyor filling 1*s*. 3*d*. (9*d*. and 6*d*. respectively). In most cases a considerable saving shown. especially in stonework, but the amount varies considerably according to circumstances.

On the Continent shaking trough conveyors are much used, and are also coming into use in th country. (See *Glückauf*, vol. 61, 1925, pp. 89–149, and vol. 63, 1927, p. 1449).

Face loaders are coming into use in the U.S.A. Amongst the leading types are :

O'Toole loader—undercuts the coal so that it falls on to a belt conveyor.

Jeffrey loader—somewhat similar in principle ; it has been introduced into Great Britai

Wilson chain loader—has gathering arms combined with a conveyor.

Joy loader—is a combined digger and conveyor.

Goodman machine—somewhat similar in principle.

Myers Whalley—mechanical shovel loading into tubs.

Jeffrey Co. and others make scrapers combined with conveyors.

Wages and general costs may be taken as 50 per cent. higher in 1927 than all those her given.

The 'Hardiax' Coal Cutter.

(*The Hardy Patent Pick Co., Ltd., Sheffield.*)

This cutter consists essentially of a long stroke air-drill, which is fixed in position and hel up to its work by means of a solid drawn steel tube provided with powerful jack-screw an toothed head and foot. The machine is seated in a cone cup forming part of a hinged clam

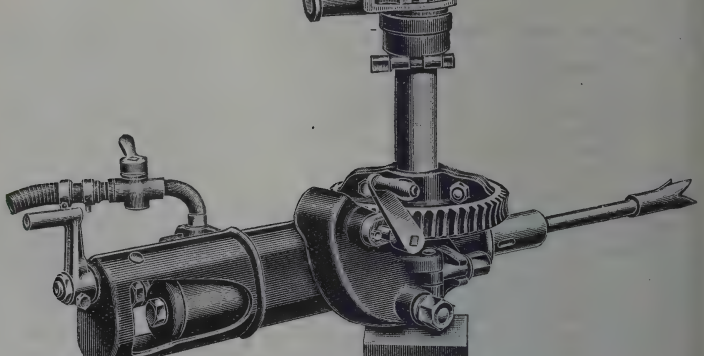

Fig. 8.—The 'Hardiax' Coal Cutter.

attached loosely to the column. This clamp carries a worm, the teeth of which mesh with those of a worm-wheel bolted rigidly on the column. By turning the worm-handle the coal cutter is caused to move around the column, whilst the forward movement into the coal is obtained by the feed screw controlled by a handle at the back of the machine. Figs. 8 and 9

give side views of the complete apparatus fixed for work at floor level. The machine may be fixed to cut at any height between floor and roof. The friction between the hinged clamp carrying the machine and the column itself is regulated to a nicety, relieving the worm of the shock of the recoil without in any way impeding the free movement of the machine right and left across the coal face.

When air is admitted to the machine the rapid and powerful blows quickly cut away the coal or other material, whilst the machine is swung right and left by the worm gear and fed forward as is necessary. An arc-shaped and continuous channel or undercut is thus speedily made, increasing in depth and width as each successive length of cutter-bar is inserted in the piston of the machine.

As soon as the desired depth is attained at the centre of the working place the operator commences to play in gradually decreasing sweeps upon the right- and left-hand sides of the arc-shaped cut, using longer cutter-bars where necessary until the undercut or channel is of uniform depth at every point, and square at the sides and corners. When pillars are taken out, or in working on a longwall face, the successive cuts break into one another, giving a continuous undercut of perfectly even depth the whole length of the coal face, whatever this may be. The cut may be any width up to, say, 20 ft. from one setting of the column. The depth of the cut is generally from 4 ft. to 6 ft. and the height 3¼ ins. to 4¼ ins. The diameter of the cutters is varied to suit different requirements.

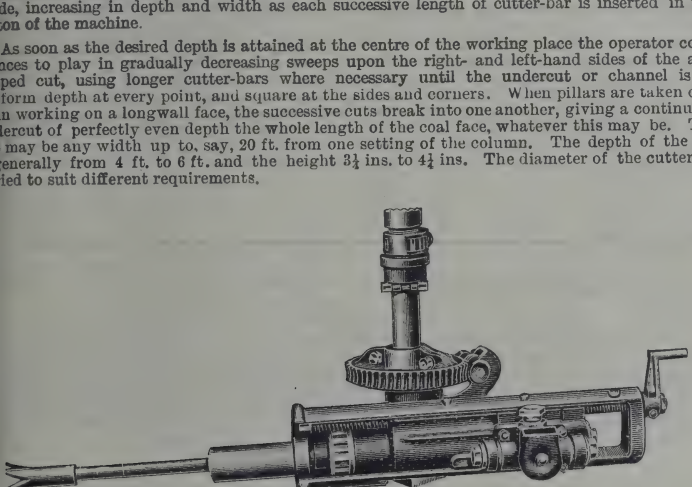

FIG. 9.—THE 'HARDIAX' COAL CUTTER.

The special constructional features of the machine are: (1) Crucible Cast Steel Cylinder. (2) Crucible Cast Steel Valve Box. (3) Crucible Cast Steel Cradle. (4) Crucible Cast Steel Gears. (5) Valve and Main Piston Hardened and Ground.

The machine is provided with a new patented piston valve action, giving great cutting power with low air consumption.

The air-pressure should, preferably, be from 40 to 60 lbs. per sq. in. or more, at which pressure the air consumption is approximately 120 cub. ft. free air per minute.

Shaft Pillars.

The 'draw' in ordinary Coal Measure strata, practically horizontal, is generally between 5° and 12° to the vertical. In Staffordshire 'draws' between 8° 45′ and 11° 10′ were observed in strata dipping 1 in 24 (W. Hay, *Trans. Inst. Min. Eng.* xxxvi. p. 47). The Final Report of the Coal Conservation Committee (Cd. 9084), 1918, p. 64, implies that the maximum angle of draw to be expected is 26° 35′.

There are reasons for assuming that the angle of draw in practically horizontal strata equals $45° - \frac{\text{angle of repose}}{2}$. For inclined strata the following formula is suggested:

$$f = b + 40 \tan (d° - 5°) \text{ and } f_1 = b - 20 \tan (d° - 5°),$$

where f is the angle of draw on the rise side of a pillar or due to workings to the dip, f_1 on the dip side of a pillar or due to workings to the rise, b the angle of draw (measured to the vertical) in horizontal strata, and d the dip of the strata measured to the horizontal. When d is $< 5°$, f and f_1 are taken as equal to b, and where d is $> 30°$, f and f_1 are taken as for 30°. For low values of b, f approximately equals b, and f_1 approximately equals 0; f_1 can never have a negative

value, but the formula is not to be relied on for values of b of less than 10° (*Trans. Inst. Min. Eng.* 1922). The following values of f and f_1 are calculated from the above formula in order to show its application :—

d.	Values of b.											
	10°				15°				20°			
	f.		f_1.		f.		f_1.		f.		f_1.	
Deg.	Deg.	Min.	Deg.	Min.	Deg.	Min.	Deg.	Min.	Deg.	Min.	Deg.	Min.
5	10	—	10	—	15	—	15	—	20	—	20	—

30	28	39	0	40	33	39	5	40	38	39	10	40

In Coal Measure strata b approximates to 10°, in Secondary strata to 20°, and in unstratified surface deposits to 30°.

In Westphalia (*Zeitsch. f. B. H. u. S. W.*, 1897) the draw in the Coal Measure has been found to be 15° on both rise and dip sides when the dip of the seam is $<$ 15° ; for dips exceeding 15°, the draw is 15° on the rise side and increases uniformly up to 35° on the dip side, reaching this value with seams dipping 35°. In the overlying clay deposits the draw is uniformly about 20°. The depth of subsidence is kT cos a, where T is the thickness of the seam and a its inclination; k is a coefficient, which is 0·8 when the goaf is not stowed at all ; with a well-stowed goaf, k is 0·4 when a is 0° to 10°, 0·3 when a is 10° to 35°, and 0·25 when a is 35°.

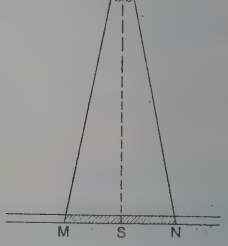

FIG. 10.

When a pillar is required to protect a colliery shaft or some structure on the surface, its dimensions can be obtained from the above formula. Thus, let it be required to determine the pillar to be left in to protect a point P (figs. 10 & 11) on the surface; let the depth of the seam be PS = D; then in a seam practically horizontal a circle, described with S as centre and radius x (SM or SN) = D tan b, will give a sufficient pillar. If the seam is inclined at an angle of d°, determine f° and f_1° as above. In fig. 11 let SB = y and SD = z, then $y = \frac{\text{D tan } f}{1 + \tan d \tan f}$, and $z = \frac{\text{D tan } f_1}{1 - \tan d \tan f_1}$.

Through P draw MN in fig. 1, with PM = PN = x as before. On the rise side of MN set out the

emi-ellipse MBN with $2x$ as the minor axis and $2y$ as the major axis, and on the dip side of MN ct out the semi-ellipse MCN with $2x$ as the major axis and $2z$ as the minor axis. This gives the lan of a pillar to protect the point P; if preferred, the rectangle circumscribing the figure formed y the two semi-ellipses may be used.

Another method, being practically that of Mr. T. A. O'Donahue, is as follows:—If D be the lepth of the seam and T its thickness, in a horizontal seam a pillar of radius R should be set out such

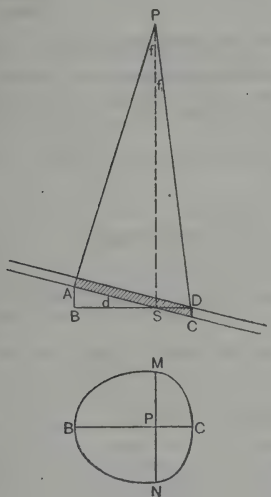

FIG. 11.

that $R = (0{\cdot}19 + 0{\cdot}01\,T)D$, all dimensions being in fact. If the seam is inclined at an angle $d°$ as above, the distance from the vertical through the point to be protected to the edge of the pillar on the rise side should be $R + \frac{2D}{3}\left(\frac{\tan d}{1 + \tan^2 d}\right)$, and on the dip side $R - \frac{D}{3}\left(\frac{\tan d}{1 + \tan^2 d}\right)$. A circular pillar should be set out with radius $R + \frac{D}{6}\left(\frac{\tan d}{1 + \tan^2 d}\right)$; the centre of the circle being at a distance $\frac{D}{2}\left(\frac{\tan d}{1 + \tan^2 d}\right)$ to the rise side of the point S. If a rectangular pillar is preferred, the square circumscribing this circle may be set out. Various other formulas have been proposed, but the two above given appear to be satisfactory.

If an area on the surface is to be protected instead of a point, a number of suitable points on the periphery of the area (e.g. the corners of a rectangle) should be selected and the protecting pillar for each be determined as above; the irregular figure thus obtained should be enclosed in any simple geometric form, re-entering angles being avoided. In a case like this, where so much uncertainty prevails as to the correct solution, an approximate result is all that can be arrived at, and a liberal margin should be allowed for safety.

Bord and Pillar working.—Pillars may be square but are mostly rectangular, sides varying from 30 to 80 yds.; 30 yds. by 40 yds. to 40 yds. by 60 yds. are usual sizes. Some engineers give areas proportional to depth; for seams 100 to 200 yds. from surface, pillars about 30 by 40 yds.; 200 yds. to 300 yds., 35 by 50 yds.; 300 to 400 yds., 40 by 60 yds.

The Coal Conservation Committee of the Ministry of Reconstruction recommends the following proportions :—

Depth from Surface.	Area of Pillar.
< 100 yds.	300 sq. yds.
100–200 ,,	500 ,,
200–300 ,,	800 ,,
300–400 ,,	1100 ,,
400–500 ,,	1400 ,,
500–600 ,,	1700 ,,

In *panel working* a rib 30 to 60 yds. wide is left between the districts, the latter being usually 20 to 50 acres in area. In American mines the width of rib is often determined by the expression T (5 + 0·01 D), where T is the thickness of the seam and D its depth below surface.

Welsh Stall working.—Single stalls are usually about 12 yds. wide with 12-yd. ribs, double stalls up to 18 yds. wide with 24-yd. ribs between them. In America the following method is sometimes used :—

Width of pillar $W = \frac{T\ D}{100}$, and width of stall $= \frac{D}{W}$, where T is the thickness of seam and D its depth, both in feet.

Subsidences.

According to O'Donahue, the working out of a coal seam 4 ft. thick will cause a subsidence of the surface of 3 ft. if the seam be not more than 200 yds. deep, and from 12 to 18 ins. if it be 800 yds. deep. It was shown that at Monkwearmouth, working two seams 6 ft. and 4 ft. thick respectively at depths of 1,725 ft. and 1,600 ft., caused surface subsidences of 6 ft. to 6 ft. 9 ins.

At Dunkirk collieries working two seams 5 ft. and 6 ft. thick, 50 yds. apart, at a depth of 445 yds., caused a subsidence of 6·8 ft. in five years and 8·92 ft. in ten years, after which it ceased.

In Staffordshire working a 5 ft. seam at a depth of 1,626 ft. caused surface subsidences varying from 1·34 to 1·47 ft.: these reached their maximum in about 29 months.

Final subsidence at the surface is equal to the thickness of the seam actually worked out (i.e. the thickness of the seam after allowing for any stowage) less the expansion due to the breaking up of the superincumbent measures. If t is the thickness of the seam and d the depth of the seam both in feet, and k the coefficient of expansion of the strata, the surface subsidence equals $t - kd$; in ordinary coal measures with seams of moderate thickness and at moderate depths k appears to be of the order of 0·2 per cent., so that if D is the depth of the superincumbent strata in hundreds of feet, then the subsidence equals $t - 0{\cdot}2$ D feet. The coefficient appears to increase with increasing thickness of the seam, which gives the strata more room to break, and it decreases as depth increases, probably because the weight of the overlying strata re-compresses to some extent the strata expanded by fracture, and this effect appears to be sufficiently well marked to prevent $t - kd$ ever coming down to zero, though it is not impossible that it might do so in the case of narrow seams at very great depth.

There are too few data available to give numerical expressions for the above general statements.

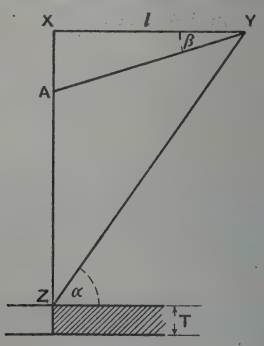

FIG. 12.

Besides the vertical subsidence over the worked-out area, a zone of draw exists over the solid coal, the breadth of which = depth of seam × tan angle of draw as given above. Let XY, fig. 12 (p. 2586), represent the zone of draw.

Let S = XA be full vertical subsidence; l = XY be length of draw (width of zone of draw); H = depth of seam; T = thickness of seam; $\alpha°$ = angle of draw measured to the horizontal, said to be about 70° in coal measures; $\beta°$ = angle of inclination of drawn surface.

There is a horizontal displacement from Y to X, and this is a maximum in the middle of the zone of draw, becoming zero at X and Y.

Tan $\beta = \frac{S}{l}$ $l = H \cot \alpha$. For seams 4ft. to 10 ft. thick, S = (0·5 to 1·0) T, when unstowed, (0·25 to 0·5) T, when hand-stowed. Maximum horizontal displacement varies from 0·05 to 0·3 T, and = $\frac{Sl}{4H} = \frac{S \cot \alpha.}{4}$

(*A. H. Goldreich, 'Die Bodenbewegungen im Kohlenrevier und deren Einfluss auf die Tagesoberflächе.'* 1926.)

In the Zwickau (Saxony) district seams differing 15°, aggregating 28 ft., worked at depths from 2,000 ft. to 3,000 ft., cause subsidence of 70 per cent. of thickness worked by goafing, 40 per cent. by hand-stowage, 10 to 5 per cent., averaging 7 per cent., by hydraulic stowage. The angle of draw by the two former methods is 80°, flatter by last-named method. In mining under densely built-over areas hydraulic stowage gives better protection against damage than leaving safety pillars. (*Goldreich, op. cit.*)

Working Costs in Getting Coal.

Working brokens is usually about 25 per cent. cheaper than working in the whole coal.

(But see 'The Driving of Narrow Places,' by S. Walter-Brown, *Trans. Inst. M.E.*, vol. lxxiii., 1923, p. 506).

Typical examples of basis yard prices in whole coal to show relative costs:

	2 yds. wide.	3 yds. wide.
Winning headways	1*s.* 6*d.*	1*s.* 2*d.* per yard
Holing walls	1*s.* 5*d.*	1*s.* 2*d.* „
Bords	1*s.* 1*d.*	0*s.* 11*d.* „

In brokens.—Jenkins, 3 yds. wide, 8*d.*; half-pillar walls, 3 yds. wide, 10*d.*; skirtings, 3 yds. wide, 6*d.* per yard.

Allowances for wet places ½*d.* to 1*d.* per ton; for band up to 2½ ins. thick, ½*d.* per ton, with ½*d.* additional for every further inch in thickness of band. For taking down ramble 3 ins. to 6 ins. thick, 1*d.* additional per ton, with 1*d.* additional for every further 3 ins.

Longwall.—Hewing price is usually about halfway between whole and broken tonnage price. An average hewing price may be taken to be 1*s.* 6*d.* per ton for a 3-ft. seam, the price rising or falling 1*d.* per ton for every 1 in. decrease or increase in thickness of seam.

All these prices are subject to local percentage increases.

PERCENTAGES OF ITEMS IN PRICE OF COAL AT PIT'S MOUTH.

Year	1913.	1901.	1866–96.	1700–50.
	Per cent.	Per cent.	Per cent.	Per cent.

Hydraulic Stowage.—The best built packwall will compress down to 70 per cent. of its original height, whilst hydraulically stowed material will not compress to less than 90 per cent. Material used in Germany varies from sand to washery residues about 1¼ in. cube. Cast-iron pipes 6 to 8 ins. diameter are used, often lined with hard cast-iron or porcelain. A cast-iron tube 7½ ins. in diameter ⅜ in. thick will transport about 1,300,000 cub. yds. of stowage material before it is worn out. The average cost of tubes is 3*d.* per cub. yd. stowed. Average rate of stowage 25 to 30 cub. yds. per hour; some mines stow over 1,000 cub. yds. per day. The total cost of hydraulic stowage varies from 4*d.* to 1*s.* 6*d.* per ton of coals got—average appears to be under 1*s.* In a trial run in Scotland the working costs amounted to 9*d.* per cub. yd.

(Professor R. W. Dron, *Institute of Mining Engineers*, November 1923.)

According to P. Francke (*Glückauf*, 1926, p. 1156) hand stowage produces a settlement of 40 per cent. of the thickness of the seam, including 10 per cent. settlement before stowing, and hydraulic stowage a settlement of 5 to 15 per cent., averaging 10 per cent.

A modified form intermediate between hydraulic and hand stowage is described in *Ann. Mines Belg.* vol. 28, 1927, p. 501.

Colliery Consumption.

According to the Coal Conservation Committee of the Ministry of Reconstruction, 1918, colliery consumption in Britain varies from 5 to 9·43 per cent., averaging 6·8 per cent., of which 6·2 per cent. is produced by the direct combustion of coal under boilers, and the balance from outside sources. In 1923 colliery consumption amounted to 6·11 per cent. and miners' coal to 2·34 per cent. of the output, and in 1924 to 6·21 per cent. and 2·46 per cent. respectively.

The capital cost of a modern colliery may be taken at 20*s.* to 30*s.* per ton of coal got per annum.

Mining in Veins and Masses.

Methods employed in veins are:

Underhand stoping.
Overhand stoping.
Combined underhand and overhand stoping.
Rill stoping.
Shrinkage stoping or magazine mining.

Irregular deposits, wide veins, thick and steeply inclined seams may be worked by the following methods:—

Lost pillars.
Vertical slices.
Horizontal slices taken transversely.
Horizontal slices taken longitudinally.
Top slicing.
Caving.
Magazine mining.
Square set timbering.

Of these, overhand stoping is the most general, underhand stoping being only used in quite special cases, as when there is only a small quantity of payground to be taken below a given level. Overhand stoping can be used for veins of medium width, say up to 10 ft. on the average. Rill stoping is mainly employed in Western Australia. Magazine mining suits veins of any width, provided that they are not too flat, that the walls are fairly good, and that the whole of the veinstuff has to be extracted. Slicing and caving are used in wide veins and irregular masses when the value of the mineral is not great and where cheap methods of working are essential; it is largely used in the hæmatite mines of Cumberland and Lancashire. Square sets can only be used where the mineral is valuable and where large timber is abundant and cheap.

* *Third Report of Fuel Economy Committee. Brit. Assoc.*, 1920.
† Royal Commission on Coal Industry (1925).

The following classification has been drawn up by the Committee on Mining Methods of the *mer. Inst. Min. Met. Engs.*, vol. lxxii. 1925.

- Open cut with or without stripping
  - Benches
  - Glory holes and milling
  - Placer mining
    - Hand sluicing
    - Dredging
    - Hydraulicing
- Underground methods
  - Breast stoping (tubular flat-dipping deposits or beds)
    - Continuous horizon
    - Casual pillars
    - Room-and-pillar
  - Underhand stoping (veins and large masses)
    - Glory hole and milling
    - Open stope
      - With pillars
      - With stalls
      - With square set timbering
  - Overhand stoping (steep-dipping veins or masses)
    - Open stope
      - With pillars
      - With stalls
      - With square set timbering
    - Filled stope
      - Horizontal cut and fill (flat-back)
      - Inclined cut and fill (rill)
      - Square set timbering
      - Piercing or stripping
    - Shrinkage stope
    - Sub-level stopes
  - Top slicing (wide veins or masses)
    - Continuous horizon
    - Panel slicing
    - Block slicing
    - Inclined slicing
  - Caving (large masses)
    - Sub-level caving
    - Block caving
      - Undercut from main level
      - Undercut from sub-levels
      - Back caving into chutes
      - With branch raises
- Combined methods (large masses)
  - Alternate shrinkage stope, and pillar
  - Pillars mined by: top slicing, sub-level caving, or block caving
  - Square set timbering: pillars mined by slicing

See 'The Working of Unstratified Mineral Deposits' by G. J. Young, 1927.

The costs of stoping vary within very wide limits, and may be illustrated by typical examples.

In Western Australia, with the contract system in force, a miner breaks 7·31 tons of ore per shift. Formerly a miner on day's pay broke only 4 tons per shift.

In eleven of the West Australian mines treating from 9,000 to 22,000 tons of ore per month with veins varying from 4–20 ft. to 6–60 ft. in width the stoping costs per ton of ore ranges from 3. 4*d.* to 9*s.*, averaging 7*s.* This includes breaking ore, filling stopes, trucking, hoisting, etc. In the Rand it costs from 3*s.* 6*d.* to 5*s.* 6*d.* to stope a ton of milling ore in stopes 40 to 60 inches height. To these figures must be added cost of compressed air, rock drill maintenance, steel sharpening, and administration underground. The first three factors amount roughly to about 3*s.* per ton, while the last would not exceed 1*d.* In some Rand mines one man can break 12 tons per shift per machine, and uses one case (50 lbs.) of blasting gelatine to break 3·5 fathoms of ground. At other mines only 7 tons are broken per man and one case of explosives is used to break 2·5 fathoms.

In Nevada at the Silver Peak Mines each miner breaks 8·6 tons of rock per shift. The total stoping cost is 5*s.* per ton. Miners here receive 16*s.* per shift.

At the Braden Copper Mines native miners break 12 tons of ore per man per day with rock drills in moderately hard rock. The total cost per ton of ore broken, including superintendence and general charges, is given as 1*s.* 9*d.*

In Utah in quartzite with a stoping width of 10 ft., square set system, small air drills, the stoping cost per ton varies from 6*s.* to 8*s.*

At Douglas Island, Alaska, the ore is a mineralised igneous rock of fair hardness, the workabl portions of which vary upwards from 30 ft. in width. Wages 12*s*. Machine used 3¾ inche piston diameter. The following figures are taken over a year's working :—

COST OF BREAKING GROUND AT DOUGLAS ISLAND, ALASKA.

General Details.	Ready-Bullion.	700 Ft.	Mexican.	Treadwell.
Average number of drills used	10·12	11·586	14·917	39·13
Tons ore broken	151,460	238,696	232,875	830,551
Tons waste broken	2,756	—	10,509	1,670
Tons broken, total	154,216	238,696	243,384	832,221
Total footage drilled	241,679	269,990	362,519	803,542
Tons ground broken per machine per shift :

Supplies and power	1 0 0	18 2	1 0 0	1 0 0
Total	3 3 8	2 17 6	3 2 2	3 0 4
Cost per foot of hole drilled	1 10	1 8	1 9	2 0
Cost per ton of ground broken	2 10	11	2 8	2 1
Total cost of mining, including development	4 0	4 9	4 10	4 6
Percentage of total mining cost	2 9	8	2 2	1 11

In the Granite Gold Mine, B.C., on a vein of hard quartz from 8 inches to 5 feet wide dipping 35° to 50°, the stoping costs per ton are as follows :—

	s. *d*.
Stoping by hand	14 0
„ by ¾-in. piston drills	11 6
„ by 2½-in. „ „	8 4
„ by 2-in. hammer drills	6 4

Mining costs at the Elko Prince Mine, Nevada, in 1917, stoping a 2 ft. 6 in. vertical vein of hard quartz by magazine mining, using hammer drills with 1⅛ in. cruciform steel, were as follows :—

	Per Ton of Ore $
Timbering, including ore shoots	0·5588
Blacksmith	0·0995
Stoping	0·8083
Tramming	0·2822
Hoisting	0·1956
Compressed air	0·1288
Explosives, detonators and fuse	0·4452
Repairs	0·0486
Drill steel	0·0570
Supervision, taxes, assaying, etc.	0·4987
Cost per ton	$3·1227 = 13*s*.

(*Bull. Amer. Inst. Min. Eng.*, Aug. 1918.)

Costs of stoping in 1903 in two mines on Cripple Creek, Col., in narrow veins: machinemen, ; miners, $3 for 8 hour shift; coal, $4·60 per ton; timber, $20 per mile.

	I.	II.
Machinemen and miners	$0·34	$0·369
Shovellers and trammers	0·41	0·401
Timbermen	0·23	0·215
Total labour underground	$0·98	$0·985
Compressed air, rock drills, sharpening	0·15	0·179
Tramming, trams, etc.	0·03	0·034
Explosives	0·13	0·139
Timber	0·28	0·310
Hoisting and surface transport	0·23	0·254
Miscellaneous stores	0·04	0·291
Supervision and general expenses	0·23	
	$2·07	$2·192
	= 8*s.* 7½*d.*	= 9*s.* 1½*d.*

For detailed costs of mining operations in various West Australian mines, see pages 2592–595.

Drilling.

Ordinarily two men can drill double-handed 25 to 33 ft. of 1-inch holes per day in limestone, to 8 ft. in granite. With double hammers 10 ft. of 2-inch holes can be drilled in medium rock.

On the Rand generally one white man and five Kaffirs run two air-drills; in some cases one hite man and seven Kaffirs run three drills. Eight 6-ft. holes is considered a shift's work for wo machines; these holes break on an average two fathoms of ground. The cost is as follows:—

	£	*s.*	*d.*
One white man	1	5	0
Five Kaffirs		15	0
Powder for two machines		16	0
Maintenance		4	0
Total	3	0	0 per fathom.

In Chili, with native labour, contracts are let on the basis of the number of holes drilled. The ock is moderately hard.

By hand.—1,008 man-days, by single hand work, drilled 13,855 ft. at a cost of 4·1*d.* per oot. Average amount drilled per man per day 13·8 ft.

By machine.—The actual cost of drilling for one month was as follows:—164 man-days 9 hours) with two ¾-in. air drills, drilled 5,082 ft. at a cost of 1·01*d.* per foot. Average amount rilled per man-day, 31 ft.

It is well known that drilling in siliceous rocks produces a dangerous dust, recognised as the rigin of Miners' Phthisis. The amount of dust suspended in the air is tested by the Katze onimeter; the atmosphere is considered safe if there are less than 300 dust particles per c.c. Final Report of Miners' Phthisis Prevention Committee, Pretoria, S. Africa.)

The Safety in Mines Research Board has devised a filter bag connected by a flexible tube ith the hole which is being drilled; this catches the particles of dust produced in drilling. Paper No. 23, 1926.)

HAULAGE.

Rails.

Mine rails weigh 10 to 40 lbs. per yard. The following table shows the least weight that hould be used for the given loads (weight of 1 loaded tub) and low speeds:—

Loads, in cwts.	7	10	15	20	25	30
Weight of rails per yard, lbs.	10	12	15	18	20	22
Gauge of track, in inches	15–18	15–18	16–20	18–22	20–26	20–30

For speeds above 5 miles per hour heavier rails are to be preferred.

Weight of 1 mile of single track in tons = 1·571 × weight of rail in lbs. per yard.

Sleepers 2 ft. 6 ins. to 3 ft. 6 ins., usually 3 ft. apart.

Sleepers 8 ins. to 12 ins. longer than gauge of track, 3–4 ins. deep, 6 ins. wide. A pair of shplates and 4 bolts for 18 lb. rails, weigh 4–8 lbs., usually 5 lbs.; 100 dogspikes for same weigh bout 14 lbs. Weight of fishplates, bolts and spikes is approximately 1 cwt. per ton of rails.

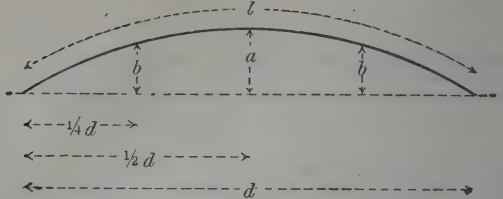
tope cut	Centre cut	Centre cut	—	—	—	—	—



To bend rails to ar
curve, let l be length of ra
r radius of curve, both
feet, a the middle ordina
in the centre of the curv
b the quarter ordinate, mi
way between a and t
end of the rail (both a ar
l in inches) :—

Then

$$a = 1{\cdot}56\,\frac{l^2}{r}, \qquad b = 1{\cdot}17\,\frac{l^2}{r}.$$

Width of track ½ in. to ¾ in. greater than gauge of wheels.

Additional width round curves :—

Gauge of track	15	18	24	30 ins.
Additional width	¼	½	⅝	¾ in.

In going round a curve with locomotive traction or on self-acting inclines, the outer r must be elevated ; with rope haulage the inner rail may have to be elevated.

Let

e = super-elevation in feet; s = gauge of track in feet; v = velocity in feet per secon
r = radius of curve in feet;
then,

$$\text{for outer rail, } e = \frac{v^2 s}{32{\cdot}2\,r}.$$

For inner rail, the elevation depends upon whether the centrifugal force due to the veloci of running is greater or less than the inward pull on the drawbar ; it will be greater at high speed say, exceeding 20 miles per hour, and less at low speeds ; under ordinary conditions at 15 mil per hour the elevation of the inner rail should be about 2 ins.

Colliery Tubs.

Colliery tubs carry from 7 to 40 cwts. of coals.

In North country average dimensions of tub body are about 3 ft. 9 ins. × 3 ft. × 2 ft. ; whe 11 ins. diameter, axles 1¾ in. diameter.

Such a tub if made of wood will carry about 7½ cwts. of coals, if of iron about 9 cwts. ; wood tubs weigh about 55 per cent. of the load, iron tubs about 50 per cent. Tubs cost approximate 15*s.* to 17*s.* per cwt., and their upkeep is about 10*s.* per annum. Upkeep is often reckoned 1*d.* per ton of coal. In South Wales much larger tubs, holding up to 2 tons, are used ; the gener tendency in other parts of the country is towards increasing the size of tubs.

Using ordinary tubs carrying about 10 cwt. of coals, it is usually reckoned that a collie requires for its equipment about one tub per ton of coals raised per day.

In U.S.A. colliery tubs carrying 1 to 4 tons are in use ; average 3-ton tub, 9 ft. 6 ins. lon 4 ft. 3 ins. wide, 1 ft. 3 ins. high.

Coefficient of friction of tubs on well-kept mine road (level), 1 per cent. to 3 per cent., avera say 1·5 per cent. ; with tubs badly greased on roads in bad repair may be two to three tim as much. Coefficient of sliding friction (wheel spragged) is from 12 to 20 per cent. ; if m coefficient of rolling friction, m' of sliding friction, the coefficient of friction with :—

1 wheel spragged $= \dfrac{3m + m'}{4}$; 2 wheels spragged $= \dfrac{m + m'}{2}$; 3 wheels spragged $= \dfrac{m + 3m'}{4}$.

Additional friction in going round curve of radius r, where the gauge of the track $= s$ (bo in feet), is $\dfrac{s}{2r}\,m'$.

Tractive effort with 18-in. wheels on good level track, 40-in. gauge, at 5 to 6 m.p.h. = 24·3 lbs. p ton with plain bearings, 12·8 lbs. with roller bearings. (*Trans. Amer. Inst. Min. Eng.*, vol. lv. p. 2

A wooden tub with plain bearings at speed of 1·75 m.p.h. showed coefficients of friction :—

$\frac{1}{30}$ with poor, $\frac{1}{54}$ with average, $\frac{1}{65}$ with good lubrication.

Coefficient on starting from rest with average lubrication $\frac{1}{30}$; tests with plain bearings collieries gave $\frac{1}{20}$, $\frac{1}{33}$, and $\frac{1}{35}$ respectively. A steel tub with plain bearings gave $\frac{1}{58}$, wi Climax bearings $\frac{1}{60}$, with Skefko ball bearings $\frac{1}{158}$; tub with Rowbotham wheels $\frac{1}{55}$.

A 9-ft. radius curve trebles, a 12-ft. radius curve doubles, the coefficient of friction with fix wheels ; loose wheels give ⅔ of increase of fixed wheels.

Starting effort to get up to a speed of 1·75 m.p.h. = 2 to 3 times the effort required to mai tain that speed with plain bearings, 1½ to 2 times with Rowbotham wheels, and 1 to 1½ times wi Skefko ball bearings. (J. Wilson, *Trans. Inst. Min. Eng.*, lxiii., p. 294.)

With 'wheel' greasers the consumption of grease averages about ¼ lb. per tub per diem f ordinary collieries.

On the average a putter can put 10 tons of coal over a distance of 200 yards (level) in a 8-hour shift.

A horse does its best work when travelling at a speed in feet per second $= \frac{1}{4}h$, where h is the eight of the horse in hands, and exerting a pull in lbs. of $\frac{60\,c^2}{h}$, where c is the circumference of the orse's chest in feet (*Baron*). Average pull is about 1¼ cwt.

Maximum gradient for hand putting, 17 per cent.
Maximum gradient for horse haulage, 12 per cent.

Gradient at which resistance of full tub downhill equals that of empty tub uphill:—Let W e the weight of a loaded tub, w that of an empty one, θ the inclination of the road, μ the co-fficient of friction :—$\tan\theta = \frac{\mu\,(W - w)}{W + w}$ (usually $\tan\theta = 0{\cdot}005$ about).

Work done in hauling a tub of weight W up or down an incline of length $l = l\,(\mu\,W\cos\theta \pm W\sin\theta)$.

Self-acting Incline.

Self-acting Incline.—Let the sets consist of n tubs each of weight w lbs., and capable of carrying V lbs. of mineral. Let the slope of the incline, assumed uniform, be $\alpha°$. Let l be the length of he rope (= length of incline) in feet, c its weight in lbs. per foot.

Let the rope be supported on rollers, the weight of which per foot of rope (= weight of one oller divided by the distance in feet between the centres of successive rollers) is r lbs. Let D e the diameter of the rollers, d of the spindle. Let μ be the coefficient of friction of the tub n rails (usually say about 0·015) and μ_1 the coefficient of friction of lubricated bearings (say ·005 to 0·008). Let F be the frictional resistance of the drum at the head of the incline, including hat of the rope coiled upon it—a figure that is always relatively small and may often be neglected. Then at any distance x feet from the starting point the full set is just able to move down the ncline when :—

$$\tan\alpha = \frac{\mu n\,(W + 2w) + \mu_1\,l(c + r)\,\frac{d}{D} + F}{nW - c(l - 2x)}$$

By putting $x = 0$ the above expression gives the angle at which the set will just start from the op of the incline.

The time occupied in descending a distance x will be:—

$$t \text{ seconds} = \sqrt{\frac{2x\,[n\,(W + 2w) + (c + r)\,l + M]}{g\left[\sin\alpha\,(nw - cl) - \cos\alpha\left(l\,(c + r)\,\frac{d}{D}\,\mu_1 + n\,(W + 2w)\,\mu\right) - F\right]}}.$$

nd the velocity in feet per second v attained after travelling a distance of x feet will be :—

$$v = \sqrt{\frac{2gx\left[\sin\alpha\,(nw - cl) - \cos\alpha\left(l\,(c + r)\,\frac{d}{D}\,\mu_1 + n\,(W + 2w)\,\mu\right) - F\right]}{n\,(W + 2w) + (c + r)\,l + M}},$$

where M is the weight of the drum and its fittings and g the acceleration due to gravity.

All the above expressions are approximations, but are accurate enough for practical purposes.

When the slope is not uniform, the calculations become more complicated. If H be the total ertical fall of the incline and L its horizontal length, it is usually sufficient, with the low radients prevailing in collieries, to use the above formulas, putting $\alpha = \tan^{-1}\frac{H}{L}$. As the enominator of the expression given above for $\tan\alpha$ increases with x, it is obvious that the ncline should, whenever possible, flatten going downwards, or be concave, though not so much o as to cause the rope to rise too high above the rails. The exact shape of the curve is not very mportant; it may with advantage be a parabola, which may be set out by making the height at any point distant y ft. horizontally from the foot of the incline $= \frac{y^2H}{L^2}$. The rope will then ollow the curve whenever the relations are such that $H = \frac{cl^2}{4T}$, where T is the tension of the ope.

Main-and-Tail Rope Haulage.

Main-and-Tail Rope Haulage.—Loaded tubs in sets up to 40 are hauled outbye by motors (steam-ngines, compressed-air engines or electro-motors) at speeds up to 20 miles per hour, whilst the mpty tubs are hauled inbye by means of the tail rope. The size of the engine depends upon the ull to be exercised when one set (nearly always the full set) is in its least favourable position. Let T be the tension in the rope in such position, made up of the weight of the set plus rope × ine of angle of inclination of the roadway, the friction of the set and of both ropes on the rollers and the pull required to accelerate the moving parts. Let C be the diameter of the steam cylinder

in inches, one of which is alone assumed to be effective at the start, let K C be the stroke of the engine in feet (K is usually $\frac{1}{2}$ to $\frac{3}{4}$), S the steam pressure in lbs. per sq. in., z the ratio of the number of teeth in the spur wheel on the drum shaft to the number of teeth in the pinion on the crankshaft, D the diameter of the drum in feet, then

$$C = \sqrt[3]{\frac{4DT}{\pi SKz}}$$

For any portion of the trip except the start (i.e. with set already in motion), both cylinders are effective, and the value as found above must be divided by $\sqrt{2}$.

These engines are usually small and run at a piston speed of 500 to 800 ft. per min.

Endless Chain and Endless Rope.

Endless Chain and Endless Rope.—Endless chain is now rarely used except on steep gradients and for short distances; it is less reliable than endless rope on long roads, requires more power and is rather more expensive to work, but admits of rather higher speeds: it may work up to 6 miles per hour; endless rope rarely exceeds 4 miles.

The following calculations apply to both methods unless otherwise stated:—

If Q be the quantity of mineral in tons to be transported per hour, W the weight in lbs. carried by one tub, V the speed of haulage in miles per hour, f the distance apart of the tub in feet, then

$$= 2{\cdot}36 \frac{V \cdot W}{Q}.$$

Endless chain is always over-tub haulage, endless rope may be over-tub or under-tub. In over-tub haulage the tubs must be so near together that the rope does not touch the ground between them. Let T be the least tension in the hauling rope or chain (i.e. between the two tubs nearest the driving pulley on the empty side), let c be the weight of the rope or chain per foot, h the height of the tub, then the distance f_1 of the tubs apart is given by

$$f_1 = \sqrt{\frac{8hT}{c}}.$$

If f is greater than f_1 empty tubs must be run on the full side.

The pull to be exerted by the engine driving the haulage is

$$\mu\left[n\ (2w + W) + 2c \cdot l\right] \cos a \pm W \sin a,$$

using the same notation as above, n being the number of tubs on any one side of the rope at any time, so that $n = \frac{l}{f}$; the lower sign is used when the gradient is with the full tubs, the upper one when against it. If this expression has the − sign, the arrangement is self-acting.

The return wheel of an endless rope haulage is often used as a tightening pulley being capable of sliding and pulled by a weight W.

Let the radius of the pulley, fig. 13, be R and of its spindle r.

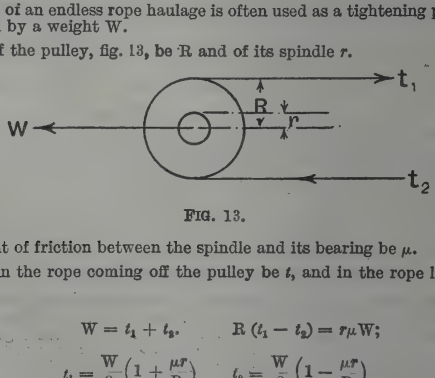


FIG. 13.

Let the coefficient of friction between the spindle and its bearing be μ.

Let the tension in the rope coming off the pulley be t_1, and in the rope leading to the pulley be t_2,

then,

$$W = t_1 + t_2. \qquad R(t_1 - t_2) = r\mu W;$$

whence

$$t_1 = \frac{W}{2}\left(1 + \frac{\mu r}{R}\right) \qquad t_2 = \frac{W}{2}\left(1 - \frac{\mu r}{R}\right).$$

See also table, p. 987.

(*Trans. Inst. Min. Eng.* xv. 1897, p. 136.)

Cost of underground locomotive haulage in Westphalia in 1912, including redemption of capital :—

Petrol	2·51 pence per ton-mile.
Continuous current (with conductors)	2·16 „ „
Alternating „ „ „	1·58 „ „
Continuous „ (with accumulators)	2·65 „ „
Compressed air	2·12 „ „

So-called fireless locomotives using superheated water, and oil or coke-fired steam locomotives are also used.

Steam Mine Locomotives.

Mine locomotives (*steam*) usually have cylinders 5 ins. to 8 ins. diameter, stroke 1½ diameters, driving wheels 20 ins. to 30 ins. diameter, wheel base 3 ft. to 6 ft., weight complete 4 to 15 tons, drawbar pull ⅓ to ¼ weight. Boiler pressure 120 to 150 lbs. Speed with full load in miles per hour ⅓ diameter of driving wheel in inches.

When D is piston diameter, *l* length of stroke, *d* diameter of driving wheel, all in inches, and P the gauge pressure of the boiler in lbs. per sq. in. then drawbar pull = approximately, $\frac{0{\cdot}85\ P\ l\ D^2}{d}$.

Compressed Air Locomotives.

Compressed air locomotives are worked at 600 to 1,000 lbs. per sq. in. gauge pressure, charged from underground receivers, in which air is compressed to 50 to 100 lbs. higher. Pressure is reduced to about 150 lbs. per sq. in. before the air enters the cylinders. The formula above given for drawbar pull may be used, P being the pressure of air as supplied to the cylinders, omitting 0·95 instead of 0·85.

Electric Locomotives.

With trolley wires, electric locomotives may use either continuous or alternating current. Weight complete is usually 7 to 15 tons, and drawbar pull 0 to ⅛, usually 0 of weight; coefficient of adhesion, 25 to 30 per cent. 75 per cent. to 80 per cent. of electric input is converted into effective effort, 1 per cent. to 2 per cent. of which will move the locomotive on the level, the remainder being available for hauling load. Speed on the level usually 6 to 8 miles per hour.

With accumulators, small locomotives are used in places for secondary haulage. The B.E.V. locomotive has a battery capacity of 193 amps. at 65 volts, and can pull or push 3-ton trucks on the level. Its use is on the increase in this country.

WINDING.

In sinking pits, the excavated material is usually hoisted in steel buckets or hoppits, usuall unguided, and usually single. The load is thus wholly unbalanced, geared engines are ofte used, and the winding speed is slow. Such buckets have capacities of 25 to 50 cubic feet, sa 30 to 60 cwts., the weight of the bucket being from $\frac{1}{2}$ to $\frac{3}{4}$ of its load. For ordinary colliery wor cages carrying two to twelve tubs are used, always in pairs running on wooden, rail or ro guides; in the Pennsylvania anthracite mines large skips are sometimes used instead of cage

Skips are largely used instead of cages in metalliferous mines; when the mineral has to b crushed the fact that the skip breaks the mineral up more than does the cage is no drawbac Self-dumping skips are used on large mines, whilst underground bins and loading stations at th shaft enable the skips to be filled very quickly. Skips usually hold from 20 to 100 cubic fee say up to about 5 tons of rock; they are made of $\frac{1}{4}$ in. to $\frac{3}{8}$ in. steel plate.

In some Illinois collieries, where the coal is to be crushed afterwards, skips about 6 ft. 6 ft. × 12 ft. 6 ins., holding about 12 tons of coal, are used; the speed of winding is up to 1,600 f per min.; the average power consumption is 0·485 kw. hour per ton of coal; up to 1,000 to of coal has been hoisted per hour from a depth of 200 yards.

On the Continent the total load lifted is about: cage 30 per cent., tubs 20 per cent., coa 50 per cent. German practice is: Let W be the weight of coals, T weight of the tubs, and Q th total weight of coals, tubs, and cage (including chains, hook, etc.); then

$$\frac{W}{T} = \frac{1}{0{\cdot}38} \text{ to } \frac{1}{0{\cdot}78}, \text{ averaging } \frac{1}{0{\cdot}56} \text{ and } \frac{W}{Q} = \frac{0{\cdot}27}{1} \text{ to } \frac{0{\cdot}44}{1}, \text{ averaging } \frac{0{\cdot}36}{1}.$$

In skip hoisting the ratio of the weight of the skip to that of the load of mineral is 0·6 : 1 to 0·9 to in hoisting in cages, the weight of cage and tubs: weight of coal: : 1·5 : 1 to 1·9 : 1 (*Zsch. B.H. u.S.W.*, 1915, p. 285). In Great Britain the cage usually weighs 35 to 45 per cent. of the tot load, or approximately as much as the useful load of coals lifted. It is carried by bridle chai usually six in number. Their factor of safety should be at least 10, and the size of the chai may be calculated thus:

Let d be the diameter of the chain in eights of an inch, and W the safe working load in to then $d = \sqrt{10W}$.

Slack adds greatly to strain on rope; according to numerous experiments, if the pull requir to lift a given cage with rope taut be taken as 1, it requires a pull equal 1·5 to 1·7 with 3 i of slack, to 2–2·25 with 6 ins., 2·25 to 2·5 with 9 ins., and up to a pull of 3 with 12 ins.

The velocity of winding varies from 15 to 75 ft. per second; a rule given by O'Donahue i allow a speed of 20 ft. per second for shafts up to 200 yards in depth, and add 5 ft. per seco for every additional 100 yards.

Wooden guides are usually 3 ins. × 4 ins. to 4 ins. × 6 ins.; rail guides 50 to 70 lbs. p yard. Rope guides made of single strand of 7 to 15 wires each $\frac{1}{2}$ to $\frac{1}{4}$ in. diameter, stretch by weight of $1\frac{1}{2}$ to 5 tons; weight is often calculated at 1 ton for every 250 yards depth of sha The friction on the guides is but small; it usually amounts to about 0·025 of the total load the rope with wooden or rail guides and 0·02 of the load with wire rope guides.

Size of Winding Engine.

To calculate the size of the winding engine the conditions of the wind must be known assumed. The diameter of the cylinders must be such that (*a*) one cylinder is capable of starti the unbalanced load and (*b*) that the two cylinders taking steam on the full stroke shall be capa of accelerating the total load to be set in motion.

If w be the weight of a cage and fittings with the empty tubs, W the weight of minerals lift per wind, h the depth of the shaft in feet, c the weight of the rope in lbs. per foot, v the veloci in feet per second up to which the load is to be accelerated during a lift of f feet; let P be t steam pressure in lbs. per sq. in., d the diameter of the piston in ins., S the length of the stro in feet, D the diameter of the drum in feet, M the weight of drum, pulleys, etc., and allowi 20 per cent. to cover the friction in the shaft, of the pulleys, drum, and engine, etc., then fulfil condition (*a*)

$$d = \sqrt{\frac{D\,(W + ch)}{0{\cdot}471\ P.S.}}. \qquad (a)$$

To fulfil condition (*b*)

$$d = \sqrt{\frac{4\,D\left[\left\{W + c(h - f)\right\} f + (W + 2w + 1{\cdot}5\,ch + 0{\cdot}5\,M)\,\frac{v^2}{2}\right]}{3\ .\ P.f.S.}} \qquad (b)$$

The larger value of d as found by (*a*) or (*b*) should be adopted.

This formula only applies to the ordinary form of winding engine with the drum carried dire on the crankshaft and the two cranks at right angles.

ST. HELENS FOUNDRY, ENGINE, AND BOILER WORKS, ST. HELENS, LANC. [See preceding page

On the average the total load, namely, coal, tubs, and cage, equals 2·66W; assuming a factor f safety of 10 and a rope of 100 tons steel, $c = \frac{26 \cdot 6W}{16{,}000 - 10h}$.

The diameter of a rope in inches equals approximately $0 \cdot 45 \sqrt{c}$; taking the diameter of ie drum as 120 times the diameter of the rope, $D = 4 \cdot 5 \sqrt{c}$.

On these assumptions, formula (*a*) becomes

$$d = 3 \cdot 856 \sqrt{\frac{\sqrt{c}\,(W + ch)}{P}}.$$

Assuming that $S = \frac{d}{6}$, and that the diameter of the drum is 120 times the diameter of the rope, lis expression takes the following form :—

$$d = 4 \cdot 59 \sqrt[3]{\frac{(W + ch)\sqrt{c}}{P}}.$$

An empirical formula which gives reasonably good results is :

$$d = 3 \sqrt{\frac{WD}{P}};$$

Usually $S = \frac{d}{6}$ and the length of the connecting rod is $2\frac{1}{2} - 3$ S. Average piston speed 500 ft. er min., varying from 300 to 800 ft.

If the load is partially or wholly balanced, the formula must be correspondingly modified.

Once the load has been accelerated to its full speed, the steam admission is reduced by means f valve gears with variable cut-offs, and during the last part of the wind work must be absorbed) as to retard the load and bring it to rest gradually ; powerful brakes are employed or the engine iay be reversed as well as the brakes applied.

The weight of the rope may be balanced by :—

1. Chain counterbalance, suitable for slow winding only, and adding enormously to the veight to be accelerated.

2. Balance rope beneath the cages ; this adds to the weight to be accelerated, but the chief bjection is the additional strain put upon the cappings of the winding ropes. Some engineers se a balance rope heavier than the winding rope, so as to overbalance the latter, to help the ngine to accelerate the load at start and to aid in retardation at the finish of the wind.

3. The conical or scroll drum. The ascending load is attached to the end of the rope which at the small end of the drum, and the descending load to the end at the large end. Using the ame notation as before, but calling r the mean radius of the drum, r_a the smaller radius, r_d the irger, Q_a the resistance due to the ascending load and Q_d the force derived from the descending oad and n the total number of revolutions of the drum during the wind :—

$$r = \frac{r_a + r_d}{2} = \frac{h}{2\pi n}$$

$$r_a = r\left(1 - \frac{hc}{Q_a + Q_d + hc}\right); \qquad r_d = r\left(1 + \frac{hc}{Q_a + Q_d + hc}\right);$$

$$\frac{r_a}{r_d} = \frac{Q_a + Q_d}{Q_a + Q_d + 2hc}$$

If δ be the diameter of the rope, the width of the drum will be approximately $1 \cdot 5\, n\, \delta$. Cylindro-conical drums, giving partial counterbalance (where most needed), are often used.

Flat ropes wound on a reel are equivalent to a spiral drum ; they will counterbalance in the hree main positions where

$$r_d - r_a = nt \text{ and } r = \sqrt{\frac{Q_a + Q_d + hc}{4\pi c}}\, t,$$

'here t is the thickness of the flat rope.

The time of banking varies considerably ; it may be averaged at about 10 to 15 seconds for ne deck and 25 to 45 seconds for double decks. Up to 3,000 tons may be wound in 10 hours, ut 2,000 tons is not often exceeded.

The consumption of coal in winding engines varies from 0·5 to 1·5 per cent. of the weight of oals wound. Steam consumption 50 to 100 lbs. per shaft h.p. hour.

The cost of a winding engine and boilers erected varies from about 3,500*l.* to about 10,000*l.*

The cost of winding, exclusive of interest and depreciation on the winding plant, varies from bout 3*s.* to 10*s.* 6*d.* per 100 tons wound.

Electric Winding Plants.

Electric winding plants are coming increasingly into favour; according to Mr. Mounta (*Trans. Inst. M.E.* xxxi., p. 329) the first cost of electric winders is considerably in excess of stea winders, so that interest and depreciation of the plant form serious items in the working cost Some of the large geared electric winders in use on the Rand raise a 3-ton load from a depth 2,500 ft., taking 2,000 e.h.p. An electric winder at a Durham pit raises 63 cwts. of coal p wind from 1,350 ft., uses 3-phase induction motor, 700 h.p., 2,900 volts; motor runs at 230 r.p.m geared 5·45 to 1; cylindro-conical drum 10·20 ft. diam., weighing 45¾ tons; overall efficienc 51 per cent.

A winder in a South Wales pit uses 2,000 volts alternating, lifts 55 cwts. from 600 ft., us 174 kw. per wind; drum cylindro-conical, 8 ft. to 13 ft.; overall efficiency, 48·25 per cent.

The last-named winder (Whiting hoist) shows an overall efficiency of 77 per cent.
(J. F. Perry, *Trans. Nat. Assoc. Col. Man.*, xv. p. 299.)

An electric winder is used at Orient No. 2 mine at West Frankfort, Ill. (Chicago, Wilmingto & Franklin Coal Co.). Coal skips normally weigh 10 tons, maximum weight, 11·5 tons; co dumped at shaft bottom from mine cars by tipplers; depth of shaft, 202 yds.; normal outpu 1500 tons per hour; maximum, 2,000 tons per hour; time of wind, 16 secs.; maximum windi speed, 4,000 ft. per minute; peak load during acceleration, 8,000 h.p.; two motors, each 2,000 h.p one placed at each end of drum shaft; motor generator set, 40 tons; fly wheel, 12 ft. diamete equipped with two 1,800 k.w., 600 volt, 600 r.p.m., d.c. generators, driven by a 2,200 h.p. inductio motor 220 volts, 3-phase, 60 cycles, 600 r.p.m.

The largest electric winder in Gt. Britain is at the Carlton Main Colliery, Grimethorpe; raises 300 tons per hour from a depth of 2,610 ft., and can develop 7,500 h.p. at 49·6 r.p.m.; has a 23-ton flywheel Ilgner set.

For full information on electric winders see "Electric Winders" by H. H. Broughton, 1927.

Headgears.

Headgears.—Steel-framed headgears usually range from ⅝ to 1 ton per foot of height, and cos erected 12*l.* to 18*l.* per ton; headgears composed of angles and joists only, not lattice girder weigh ⅜ to ⅝ per foot of height. Wooden headgears weigh about ¼ ton per foot of height an cost 10*l.* to 12*l.* per ton. The size of the main legs of timber headgears is given approximatel by the expression $A = 0{\cdot}03\ H^2\sqrt{W}$, where W is the total working load on the winding ropes i tons, H the height in feet of the headgear from the ground to the pulley centres, and A th area of the cross-section of the main leg; the area of the backstay = 0·64 A.
(R. Boyle, *Scott. Inst. Min. Stud.* 1908.)

Ferro-concrete headgears have been erected in several places and have proved quite satisfac tory.

Pulleys.

Pulleys.—Usually 10 to 20 ft. in diameter, mostly of the same diameter as the drum. Pillo blocks may be carried on strong springs to diminish shock at starting.

If W be the weight of a pulley in cwts. and d its diameter in ft., $W = 9{\cdot}2\,(d-8)$ approximatel for large colliery headgear pulleys. $W = \frac{d^2}{4}$ is a useful approximation, but is too low for pulley under 6 ft. in diameter.

The angle of lead from the drum to the head gear pulleys should not exceed 2° on either side f the centre line; the horizontal distance between the drum and pulley centres should not exceed 50 ft., otherwise the rope is apt to surge.

The first Koepe winder, supported directly over the shaft, thus dispensing with the usual eadgear and pulleys, to be erected in this country, is in operation at Plenmeller Colliery, orthumberland. The Koepe driving pulley is 11 ft. 6 ins. in diameter, driven through single eduction gearing at 200 r.p.m. by a 240 h.p., d.c. motor, fitted with Ward-Leonard control. urrent is supplied by a 200 kw., 350 volt generator direct coupled to a 3-phase 50 cycle 600 volt nduction motor running at 730 r.p.m. The depth of the shaft is 815 ft., and single deck cages aking 3 tubs holding altogether 48 cwts. of coal are used. The whole of the hoisting machinery contained in a two-storied steel-framed house with corrugated iron sides and roof mounted on a ull lattice-girder framework. An overall efficiency of 60 per cent. is attained.

(*Trans. Inst. Min. Eng.*, lv. p. 170.)

Another has been erected at Murton Colliery, Co. Durham. The motor here is 400 h.p. on a ,000 volt, 40 period current; it draws 4 tons of coals per wind from a depth of 1431 ft. in 80 secs., he coefficient of friction between rope and driving pulley has been found to be 0·407. The verall efficiency is 61 per cent. (G. Raw, *Trans. Inst. M.E.*, vol. lxxiii., 1927, p. 380.)

On the Rand, hoisting with skips costs 8*d.* to 1*s.* per ton from depth of about 1,000 ft.

ROPES FOR HAULING AND WINDING.

Weight in lbs. of rope of circumference C inches per yard :—

Of ordinary hauling or winding ropes with hemp cores about	0·55 C^2.
„ wire ropes with wire cores . . . . „	0·6 C^2.
„ flattened strand rope	0·57 C^2.
„ locked coil rope	0·75 C^2.
„ all-steel guide ropes	0·65 C^2.
„ hemp ropes	0·2 C^2.
„ coir „	0·12 C^2.
„ aloes „	0·1 C^2.

The number of wires of diameter d in a wire rope of diameter D is approximately $0·75 \frac{D^2}{d^2}$.

The breaking strength in tons of ropes of circumference C inches is approximately :

Ordinary hemp rope	0·3 C^2.	Aloes fibre rope .	0·4 C^2.	Mild steel . .	1·75 C^2.
Best „	0·6 C^2.	Charcoal iron .	1·5 C^2.		

For ordinary ropes (with hemp cores) of	80–90 T wire . . .	3·3 C^2.
„ „ „	90–100 „ . . .	3·7 C^2.
„ „ „	100–110 „ . . .	4·0 C^2.
„ „ „	110–120 „ . . .	4·4 C^2.
„ „ „	>120 „ . . .	4·6 C^2.

The weight of rope in lbs. per yard which shall have a breaking strength of W tons = kW, where k has values :

For 80–90 T wire .	0·167	For 100–110 T wire .	0·138	For >120 T wire .	0·120
„ 90–100 „ .	0·148	„ 110–120 „ .	0·125		

If S is the breaking strength of the wire in tons, the strength of the rope is approximately

$$0·04\ C^2\ S.$$

If a rope n yards in length is required to carry a load of W tons with a factor of safety of f, using wire having a breaking strength of S tons per sq. in., weight of rope in lbs. per yd. is

$$\frac{2{,}240\ f\ W}{160\ S - f n}, \quad \text{or} \quad \frac{2{,}240\ k\ f\ W}{2{,}240 - k\ f\ n}.$$

If 160 S is $< f n$, a stronger wire must be selected.

The British Association of Wire Rope Manufacturers has adopted the following distinctive nomenclature for the steel wire ordinarily used in rope manufacture :—

Description.	*Breaking Strain.*
Best patent steel wire	80 to 90 tons per sq. in.
Special improved patent steel wire	90 to 100 „ „
Best plough steel wire	100 to 110 „ „
Special improved plough steel wire	110 to 120 „ „
Extra special improved plough steel wire . . .	above 120 „ „

Mild steel used for special purposes has breaking strength of 26 to 80 tons per sq. in.

For wire ropes of	6	strands of	7	wires	deduct	5%	off sum of strength of wires.				
„	6	„	12	„	„	10%	„		„	„	„
„	6	„	30	„	„	15%	„		„	„	„
For locked coil ropes deduct . . .						5%	„		„	„	„

Wire rope should never be bent round a drum or pulley whose diameter is less than 100 I or 1,000 d; 150 D, or 1,500 d, are preferable, and the respective coefficients 120 and 1,200 a quite frequently employed. In Belgium, diameters of pulleys greater than 750 d for flat rope or greater than 1,000 d for round ropes, are allowed. In the Pas de Calais the following propo tions of drum diameter have been adopted: for Lang's lay, greater than 68 D, for flattene strand greater than 72 d, and for lock coil, greater than 80 d.

(J. F. Perry, '*Mining Engineer*,' vol. iv., No. 34, p. 24.)

The maximum bending stress in pounds per square inch produced by bending a rope roun a pulley of diameter $\triangle$ is theoretically $E\frac{d}{\triangle}$, where E is the modulus of elasticity of the wi used; it ranges from 10,000,000 to 30,000,000 lbs. Owing to the strain not acting directly right angles to the cross section of the whole rope, it is found in practice that the mean stre is more correctly represented by the expression $\frac{3}{8}E\frac{d}{\triangle}$. According to R. W. Chapman (*Pro Austr. Inst. Min. Eng.*, vol. iii., No. 3, April 1908), if a is the angle of pitch of the wires in strand and b of the strands in a rope, the bending stress is $E\frac{d}{\triangle}\cos^2 a \cos^2 b$.

If s be the mean bending stress as above, T the breaking strength in lbs. per sq. in., m th factor of safety (ratio of total breaking load to total working load), W the total load to be carrie and A the total cross-section of steel in the rope, $A = \frac{mW}{T - s}$.

For ordinary winding ropes $A = 0{\cdot}6\ D^2$ approximately.

Factor of safety for haulages for 5 to 6, for winding ropes 8 to 10.

Coefficients of friction of wire rope :—

Dry rope on a grooved iron drum . .	0·120	Greased rope on a wood filled sheave	0·14
Wet „ „ „ „ . .	0·070	Dry rope on rubber or leather filling	0·49
Greased „ „ „ . .	0·70	Wet „ „ „ „ .	0·40
Dry rope on a wood filled sheave . .	0·235	Greased „ „ „ .	0·20
Wet „ „ „ „ . .	0·170		

According to G. Raw (*Trans. Inst. Min. Eng.*, iv., p. 180) the coefficient of friction of slightly oiled flattened strand rope upon an elm-filled sheave, fibres on end, is between 0·3 an 0·35.

The resistance to bending of a rope under tension T lbs. round a pulley of radius r ft. $= 1{\cdot}26 - 0{\cdot}002276\frac{T}{r}$ (*Weisbach*). The maximum admissible stress in a medium wire rope may be taken a averaging 5,000 times the weight of 1 foot of the rope.

Flattened Strand Ropes.

Flattened strand ropes are constructed of strands each of which has a flattened surfac exposed for wear throughout its entire length, so that the wear due to friction in working ove pulleys is distributed over a larger number of wires than is the case with ordinary round strande

Flexible Crane Rope
(Non-rotating).

ropes. In the latter the wear is very severe on the crown wires of each strand, which are, consequently, considerably reduced in sectional area before any appreciable wear has taken place in the adjoining wires. The smooth surface of flattened strand ropes materially reduces wear and tear on drums and pulleys; owing to the wear being so light on the ropes, it is not necessary to have so large a margin between the working load and the breaking strain as in ropes of ordinary make. Being more compact, they contain a larger metallic area than ordinary ropes, and therefore a flattened strand rope is of smaller size than an ordinary rope of equal breaking

strain, and is not so liable to be forced out of shape by the crushing stress it has to sustain. When required, flattened strand ropes are made non-spinning for winding and sinking purposes. They are very suitable as balance ropes, as, being absolutely dead, they can be used with or without pulleys in the sump.

Flattened strand haulage ropes splice more effectively than ordinary ropes, as the core is slightly smaller than the strands, and there is consequently less risk of the splice drawing. This construction is of special utility in ropes used for power transmission purposes, aerial ropeways, etc., where an efficient splice is essential. The greater surface of flattened strand ropes increases the holding power of grips or clips used in haulage work. For use on cranes and lifts, these smaller ropes possess special advantages, as the construction gives greater strength than the ordinary make without increase in size or loss of flexibility. Non-rotating ropes of special formation are in great demand for crane work, particularly for cranes used in the erection of large buildings, and on quays and shipping wharves, as any tendency of the rope to spin is entirely obviated.

NOTE.—The figures given above are calculated on flattened strand ropes, having six strands with hemp main core, see No. 49K, p. 2604.

(*Wrights Ropes Ltd., Birmingham.*)

Locked Coil Ropes.

Locked coil ropes are in many cases advantageous where heavy loads have to be raised from great depths. Strength for strength, they are of less diameter than ordinary ropes, and consequently admit of corresponding reduction in width of drum, thus minimising lateral friction on drums and pulleys. They are absolutely free from any tendency to rotate, and are therefore of special utility in sinking operations and for winding in shafts where there is not much clearance, as the possibility of collision between the cages is obviated. Frictional wear on guides is also very much reduced by the use of locked coil ropes in winding. They are of longer duration than any other form of rope, as owing to their smooth surface the external wear is evenly distributed over the periphery of the rope, and internal friction, which is so marked a feature of ordinary ropes, is reduced to a minimum. In the event of any wire being broken in use, it is held in position and does not, as in an ordinary rope, unravel and lay across the adjacent wires, causing other fractures in working over drums and pulleys. The tendency to internal corrosion is less in locked coil ropes than in any other type of rope, as during the process of manufacture the successive annular layers of wires of which the ropes are composed are coated with a special

rust and acid-proof lubricant, which cannot be worn off during work owing to the protection afforded by the interlocking wires of the outer cover. In consequence of the wear on these ropes being so light, they may be worked with a lower margin of safety than is the case with ordinary ropes, as with the latter, in estimating factor of safety required, provision has to be made for the rapid wear which takes place.

As guide ropes, the advantages of the locked coil construction may be readily understood when it is borne in mind that, in the event of a rod breaking in the ordinary twisted guide rope, it would strand out from the rope, and be caught by the cage gland with disastrous results; in a locked coil rope the broken rod would be securely held in position.

Locked coil ropes are eminently desirable as standing ropes for aerial ropeways, as their smooth surface affords very easy running for the wheels of the carrier; consequently less haulage power is required and wear and tear considerably reduced.

Steel Wire Ropes for Oil-well Drilling.

Wire ropes are largely employed in drilling oil-wells, particularly where the American syst of drilling is in use, which is known as the Californian Cable Rig. This system uses a drilli line for manipulating the tools, a casing line for manipulating the casing, and a sand line cleaning out the wells. The two former are generally 6 × 19 construction, and the latter 6 ×

The Russian or Galician system employs jointed rods in place of drilling lines, but wire ro are used for cleaning out the wells and for manipulating the casing and the string of tools. T sand, pump, or bailing lines are usually 6 × 7 construction, and the other ropes, which run to $1\frac{1}{2}$ ins. diameter, are 6 × 19, 6 × 24, or 6 × 30.

Oil-well drilling, being exceptionally severe, calls for ropes of high quality.

Galvanized ropes are sometimes advisable on account of the corrosive action of the wa in the wells.

It is a matter of general practice to have the drilling ropes left-hand lay.

Electrical Cables for Collieries.

Pumps and Pumping.

Cornish pumps from 4 ft. to 12 ft. stroke, 6 ins. to 30 ins. diameter, 12 to 16 strokes per mi piston speeds vary from 60 to 120 ft. per min. A rule sometimes adopted is that speed in feet second $= \sqrt{l}$, where l is the length of stroke in feet. Ram pumps work at speeds of 100 to 200 per minute.

If n be number of complete strokes (i.e. up and down strokes) per min., and d the diame of the ram or bucket, the theoretical discharge G in gallons per min. is given by $G = 0{\cdot}034d^2$ The actual discharge is less than this by the slip, which ranges from 3 per cent. to 30 per ce

* Printed and published by H.M. Stationery Office. Price 1s. net; 1s. 2d. post free.

n extreme cases. In practice it is usually between 10 per cent. and 15 per cent. It must ıe deducted from the theoretical discharge to get the actual discharge. Maximum velocity ıf water in rising main 200 to 300 ft. per min., rarely exceeds 100 ft. in small pumps; maximum velocity in windbore, 40 ft. per min.

Pressure at bottom of rising main = pressure due to static head + pressure required to overcome resistance of pipe.

If v be the velocity of discharge in feet per second, H the vertical head in feet, L the length n feet of the pipe, D its diameter in inches, and P the total pressure at bottom of rising main, :hen,

$$P = 0{\cdot}341\ D^2\left(H + 0{\cdot}024\left(\frac{L}{12D}\right)^4\frac{v^2}{2g}\right).$$

The pressure in the steam cylinder must be capable of overcoming this pressure, allowing for the mechanical efficiency of the engine (say 0·66).

The content of a pipe in gallons of water = $0{\cdot}034\ D^2L$.

The thickness of a pipe can be calculated thus:—

Thickness in inches = 0·000125 P.D. + 0·5.

Thickness of pump-barrel = $0{\cdot}5 + \frac{\text{P.D.}}{2{,}000}$, where P is pressure in lbs. per sq. in.

Weight of pipe in lbs. = $2{\cdot}5\ L\ (D^2 - d^2)$, where D and d are external and internal diameters. The flange = weight of 1 ft. of pipe.

Horse-power in the water lifted = $\frac{g\ H}{3{,}300}$, where g is the actual delivery in gallons per min.

The 'duty' of a Cornish pumping engine is the number of millions of pounds of water lifted one foot high by the consumption of 112 lbs. of coal (before 1856 of one bushel = 94 lbs., and in America of 100 lbs. of coal) under the boilers. To convert duty into lbs. of coal burnt per h.p. in the water, divide 222 by the duty. It is always theoretical discharge that is taken in calculating duty. Cornish engines have worked with as little as 1·5 lb. coal per h.p.; 2·5 to 3 lbs. is a usual figure.

For double-acting pumps the formula for discharge previously given becomes

$$G = 0{\cdot}068\ d^2\ n.l.$$

If A be the area of the piston, n number of strokes per minute, S length of stroke, b the height of the water barometer, l the length of the windbore, a its area, h the vertical height of the suction lift, g the acceleration of gravity,

$$a > 0{\cdot}0055\ \frac{An^2\,Sl}{g(b-h)}$$ for single-acting pumps, and $> 0{\cdot}00275\ \frac{An^2\,Sl}{g(b-h)}$ for double-acting pumps,

or the piston will rise faster than the water can follow it, and hammering will result.

The air-vessel should have a volume = 4 times that of barrel for single-acting, and 1·6 times for double-acting pumps. (*Weisbach.*)

Centrifugal Pumps.

Let u be peripheral velocity of impeller in ft. per sec.

- r radius of the impeller in feet.
- n number of revolutions per second.
- d depth of openings in impeller in feet.
- i number of impellers in series.
- h height of total lift in feet.

then

$u = 2\,n\,\pi\,r$. Velocity of radial water discharge from impeller = K u, where K is a coefficient between 0·1 and 0·3, averaging 0·2. Quantity of water discharged per second = $K\,u\,2\,\pi\,r\,d = 4\,K\,n\,\pi^2\,r^2\,d$ cub. ft. $h = c\,i\,\frac{u^2}{2g}$, where c is a coefficient that varies considerably, but is mostly between 0·75 and 1.

Mechanical efficiency (m) is between 0·5 and 0·8, usually about 0·7.

Hence h.p. required $= \frac{8\ K\ c\ \pi^4\ n^3\ r^4\ i\ d}{8{\cdot}8\ m\ g}$, or, taking average values, h.p. = about $\frac{2}{3}\ n^3\ r^4\ i\ d$.

Direct coupled motor-driven centrifugal pumps to pump 1,500 gallons p.m. to a height o 1,000 ft. have been found to have an overall efficiency of 71·6 per cent.; electrically driven ran pumps would have a similar efficiency of 80 per cent. *(Prest & Leggat.)*

(See also PUMPS, p. 1330).

VENTILATION.

MINE GASES AND VENTILATION.

Normal air contains 79 vols. nitrogen, 21 vols. oxygen, carbonic acid 0·06 to 0·11 per cent With 17·0 vols. of oxygen a candle is extinguished, but breathing is still possible; with 15·2 vols of oxygen breathing becomes more difficult; with 10 vols. of oxygen, very difficult; and with 5 or 6 vols. practically impossible. Prussian rule for volume of air in mines is 70 cubic fee per min. per man underground, reckoning each horse as four men; it must never amount t less than 53 cubic feet per ton of daily output.

Approximately in Great Britain 5·8 tons of air pass through coal mines per ton of coal raised The blood in a man's body is capable of absorbing about one pint (about 20 per cent. of it volume) of either oxygen or carbonic oxide when saturated. If it be half saturated with carboni oxide, unconsciousness sets in, and with higher proportions death follows. In air containin 0·1 per cent. of carbonic oxide the blood would become half saturated in about an hour in the cas of a man at rest, and in about half an hour in the case of a man taking exercise. Anything abov 0·15 per cent. of carbonic oxide must be considered dangerous; 0·16 per cent. will cause sligh distress to mice in an hour, 0·2 per cent. distress in 8 minutes, 0·3 per cent. distress in 4 minutes 0·45 per cent. distress in 2 minutes and collapse in 4 minutes, 0·57 per cent. distress in 1 minut collapse in 6½ minutes, and death in 12½ minutes. With canaries 0·09 per cent. causes distres in one hour, 0·15 per cent. distress in 3 minutes, fall from perch in 18 minutes, 0·2 per cent. distres in 1½ minutes. fall from perch in 5 minutes, and 0·3 per cent. fall from perch in 2½ minutes.

Fire-damp.—Fire-damp consists essentially (up to 95 per cent. or more) of marsh gas o methane, CH_4, the remainder consisting of nitrogen and carbonic acid; hydrogen and som of the higher hydrocarbons have also been found in some samples. Haller and Moureu hav found helium with traces of neon (0·003–0·05 per cent.), and argon with traces of krypton an xenon (0·003–0·04 per cent.) in fire-damp. A mixture of air and marsh gas will explode if th mixture contains between 5 and 15 per cent. of marsh gas by volume. The maximum of explosiv violence is attained with 9 to 10 per cent. of marsh gas. The igniting point is between 650° and 750° C., and there is always a perceptible 'lag' or delay in the ignition, the amount o which depends upon the temperature. According to Taffanel and Le Floch, mixture containing only 3 per cent. of marsh gas will ignite at 680° C. and as much as 30 per cent. a 875°. In a mixture of 6·5 per cent. of marsh gas with air, the quantity of gas burnt per second varies from 0·00075 per cent. at 535° C. to 0·05 per cent. at 640° C. According to H. Le Chatelie the igniting point of acetylene is 450° C., hydrogen 550° C., methane and carbonic oxide 650° C The velocity of propagation of ignition of methane ranges from 0·03 m. per sec. with 6 per cent of methane to a maximum of 0·61 m. per sec. with 12 per cent., and falls again to 0·1 m. per sec with 16 per cent. of methane in air. The velocity of the explosive wave in a mixture of methane with pure oxygen is 2,500 m. per sec. Marsh gas has been given off in quantities up to 4,500 cubic feet per ton of coal wrought, and has been shown to exist in coal under pressures up to 40 atmospheres. It is on record that in one mine as much as four million cubic feet of fire-damp has been given off in 24 hours.

Experiments on the ignition of mixtures of methane and air by electric sparks have been recorded by Dr. Thornton (*Trans. Inst. Min. Eng.*, xliv. p. 145, and xlvi. p. 112); the most inflammable mixture is one containing about 7 per cent. of methane. With sparks between copper poles the least continuous current capable of igniting a 9 per cent. mixture was found to be:—

50	100	240	480 volts.
4·0	0·9	0·175	0·05 amps.

With iron poles slightly greater currents are required. With alternating currents of low periodicity, the current required is far greater, ranging from 3 times at 50 volts to 12½ times at 500 volts. The higher the frequency, the larger the current required for ignition.

PRINCIPLES OF VENTILATION.

The difference of pressure producing ventilating currents in mines is measured by the water-gauge; a column of 1 in. of water corresponds to about 66 ft. of air at 60° F and 30 ins. of barometric pressure. The theoretical velocity of air due to such pressure is given by the expression

$=66\sqrt{h}$, where v is the velocity in feet per second and h the water-gauge in inches. If the ction in the airways of a mine is taken into account, according to Murgue—

$$h = K\frac{l\,p\,v^2}{a} \text{ or } h = K\frac{l\,p\,Q^2}{a^3}$$

here l is the length of the air passage, p its perimeter, a its area, all in feet, and Q the quantity air in cubic feet per second. Values of coefficient K: for drifts, bricked and arched, =0·000,0012; in ordinary rock, untimbered, K=0·000,0034: timbered in the usual way, mensions taken inside timbers, K = 0·000,0057. If the quantities and velocities be given in ousands of feet per minute, these coefficients become 0·00033, 0·00094 and 0·00156 respectively; me engineers use Mr. Fairley's coefficient, which is 0·002. The critical velocity of air flowing

circular pipes $= \frac{18}{D}$ feet per min., where D is the diameter of the pipe in feet.

The work required to move a quantity Q of air under a water-gauge of h inches=5·2 hQ foot-ounds.

Mr. J. T. Storrow has found that the quantity of air flowing through material under 0·25 in. size at a slow rate varies directly with the pressure and not with the square root.
(*Trans. Inst. Min. Eng.*, lv. 313.)

The loss by scaling through packwalls, etc., would therefore be greater than in an open airway r the same difference in pressure.

Measurement of flow of air. — In a pipe circular in section a velocity equal to the mean flow at 0·15 of radius from the wall of the pipe. In a mine drift the mean of two measurements lfway between roof and floor and one-sixth of the width of the airway from either side will pproximate to the mean velocity of the air in the drift. The mean velocity is between 0·7 and 85 of the maximum velocity at the centre of the drift, averaging 0·78.

With the ordinary plain Pitot tube, if v be the velocity of airflow in feet per second and h the ater-gauge in inches, $v=66\sqrt{h}$; with the double Pitot tube (one branch facing the other pointing the direction of the flow) $v = 56{\cdot}5\sqrt{h}$.

If the pressure of air on either side of a regulator or other diaphragm with an aperture of a quare feet be determined by water-gauge, and the difference of gauge pressure be d inches, the uantity of air flowing is $40\,a\sqrt{d}$ cubic feet.

Natural Ventilation and Furnace Ventilation.

Natural Ventilation and Furnace Ventilation.—If there be two shafts, the mean temperature f the air in each of which is respectively T and t (in degrees Fahrenheit), the water-gauge due o this difference of temperature will be $\frac{H}{66}\left(\frac{T-t}{459+T}\right)$, where H is the depth of the pit, assuming that the temperature of the atmosphere is 60° and the pressure 30 ins., under which conditions cubic foot of air weighs 0·0765 lb.; under any barometric pressure of β inches and temperature Fahrenheit, the weight of a cubic foot of air is $\frac{1{\cdot}326\ \beta}{459+t}$, by means of which formula the necesary correction can be applied. The number of heat units required to produce the above water auge will be $\frac{1{\cdot}326\ Q\ \beta\ (T-t)}{459+t} \times 0{\cdot}2375 = \frac{0{\cdot}315\ Q\ \beta\ (T-t)}{459+t}$ heat units per second.

The grate area is often taken $= \frac{34}{\sqrt{H}} \times \frac{5{\cdot}2\ hQ}{550}$ sq. ft.

In practice, to pass 300,000 cubic feet of air per min. with a 2-in. water-gauge about one ton f coal is burnt per hour.

Fan Ventilation.

Fan ventilation.—If u be the peripheral velocity of the fan blades in feet per second, the heoretical water-gauge produced $= \frac{u^2}{68g} = \frac{u^2}{2180}$.

The manometrical efficiency of a fan ranges from about 0·45 for an open-running fan up to about 0·9 for a good modern enclosed fan.

The volumetric efficiency under given conditions is the volume of air actually passed by the fan divided by the volume of the fan × number of revolutions.

The mechanical efficiency is the horse-power required to drive the fan (or the fan and fan engine, as the case may be) divided by the horse-power in the quantity of air moved = $\frac{5{\cdot}2\ h\mathrm{Q}}{550}$. It varies from about 45 to about 75 per cent. in different types of fans.

The equivalent orifice of a mine $o = 0{\cdot}4\ \frac{q}{\sqrt{h}}$, where q represents the quantity of air in thousands of feet per minute, and o the area in sq. ft. The equivalent orifice of British mines is usually between 20 and 30 sq. ft.

If H be the initial water-gauge of a given fan (maximum water-gauge, produced on exhausting out of a closed vessel), the equivalent orifice of a fan, working on a mine with equivalent orifice o, should be $= o\sqrt{\frac{h}{\mathrm{H}-h}}$. The inlet area of a fan should be about 20 per cent. greater than its equivalent orifice. The equivalent orifice of a fan should be about three times that of the mine on which it works. The velocity at which air enters the fan orifice should be between 1,000 and 1,500 ft. per min. If k be the manometric efficiency of any fan, according to Murgue—

$$u = \sqrt{\frac{g\ 68\ h}{k}}.$$

To find the horse-power of a motor or engine required to drive a fan under average mine conditions, multiply the number of cubic feet of air by the water-gauge and divide this product by 4,500. Example: If a fan is delivering 100,000 cub. ft. of air at 2-in. water-gauge, what should be the horse-power of the motor or engine required to drive it?

$$\text{H.P.} = \frac{100{,}000 \times 2}{4{,}500} = 44{\cdot}4.$$ (*Machinery.*)

The average consumption of brattice cloth in U.S.A. is 1,697 sq. yds. per 100 tons of coal raised. (*Report on Brattice Cloth, U.S.A. Bureau of Mines.*)

REGULATORS.

Regulators.—If A be the area in sq. ft. of a regulator which is required to produce as much resistance to the flow of air as a roadway of length l, perimeter p, both in feet, a area in sq. ft., K = Murgue's coefficient of friction as above when the quantity of air is expressed in thousands of cubic feet per minute and the pressure in inches of water-gauge, then $\mathrm{A} = 0{\cdot}4\sqrt{\frac{a^3}{\mathrm{K}\,p\,l}}$. The regulator should be placed behind the last man in the split.

Safety Lamps.

The gauze should contain not less than 784 meshes per square inch.

TABLE SHOWING AVERAGE CANDLE-POWER OF VARIOUS LAMPS (*a*) AT BEGINNING, AND (*b*) AT END OF TEN HOURS' BURNING WITH FIVE DIFFERENT OILS.

Lamp.	No. 1 Oil.		No. 2 Oil.		No. 3 Oil.		No. 4 Oil.		No. 5 Oil.

TABLE SHOWING COST IN PENCE PER 1,000 LAMPS OF ONE AVERAGE CANDLE-POWER HOUR, WITH DIFFERENT OILS.

Oil.	Marsaut.	Donald.	Mueseler.	Davy.	'Geordie.'	Clanny.	Scotch Davy.	Deflector.
No. 1	11½	22	14½	18	16	11½	17½	11½
No. 2	19½	33¾	32	19	—	—	—	—
No. 3	25½	43	43½	26½	—	—	—	—
No. 4	35	56	59½	42½	—	—	—	—
No. 5	45½	73	75¾	43¾	—	—	—	—

The oils used were as follows :—

Oil.	Specific Gravity.	Composition, per Cent.		Cost per Gallon.
		Mineral.	Vegetable.	s. d.
No. 1	0·820	100	0	0 9
No. 2	0·841	70	30	1 6
No. 3	0·844	50	50	1 9
No. 4	0·865	30	70	2 3
No. 5	0·889	0	100	2 9

Lamps burning benzine of sp. gr. 0·765, costing 1*s.* per gallon, gave the following results :—

	Candle-power.		Cost in pence per 1,000 lamps of one average c.p. hour.
	At Beginning.	At End.	
Wolf	0·99	0·94	16½
Protector . . .	0·72	0·66	25½

Gas Caps.

Gas caps are shown in an ordinary safety lamp with the flame turned down so as just not to show any white light, when introduced into an atmosphere containing small amounts of marsh gas or methane, approximately as follows :—

2 % of marsh gas. Cap ¼ in., just visible except at extreme tip.
3 % " " " ½ in., fully formed.
4 % " " " ¾ in., well defined.
4½% of marsh gas. Cap 1½ in., well defined.
5 % " " " 2½ ins. " "
5½% " " " 4 ins. " "
6 % " " " fills the safety lamp.

Gas-testing lamps burning alcohol will show clearly as little as 0·2 per cent. of marsh gas.

Coal Dust.

Coal-dust.—Three ounces of coal-dust per cubic yard of gallery space is sufficient to produce an explosive mixture; excess of coal-dust prevents neither the initiation nor the propagation of an explosion. Coal-dust giving less than 12 per cent. of volatile matter is practically incapable of initiating an explosion. At least 50 per cent. of inert stone-dust is required to prevent the initiation of an explosion. If less than 75 per cent. of the dust passes the 200 sieve it is difficult to initiate an explosion. (*Abstracted from the Lievin experiments.*)

The temperature of ignition of coal-dust is about 1,000°C. Mixed with air and introduced into a heated vessel the temperature may be as low as 590°; there is very little lag. (*Taffanel and Le Floch.*)

The General Regulations provide that in all coal mines except anthracite mines and except mines of which the floor, roof, and sides of the road are naturally wet throughout, every road or part of a road shall be treated with incombustible dust in such a manner as to ensure that the dust on the floor, roof, and sides throughout shall never contain more than 50 per cent. of combustible matter, or else they shall be treated with water in such a manner that the dust is always combined with 30 per cent. (by weight) of water. It is provided that the percentage of incombustible dust required by this regulation may be reduced by an amount equivalent to the percentage of water present. The incombustible dust shall contain not less than 50 per cent. of material capable when dry of passing through a sieve with 200 meshes per linear inch. If more than 50 per cent. of dust is used, the percentage of fine material in such dust may be reduced proportionately, but shall not fall below 25 per cent. Representative tests must be made by the management at intervals of not less than one month, and the results posted at the pit head. The method in which the tests are to be made is fully prescribed by the Statutory Orders.

Rescue Apparatus.

There are three main types of rescue apparatus :—

(1) The supply of oxygen is maintained by means of compressed oxygen carried in steel cylinders.

(2) The supply of oxygen is obtained from liquid air.

(3) Oxygen is chemically generated from peroxides, usually sodium-potassium peroxide.

In (1) and (2) the expired carbonic acid is absorbed, usually by caustic soda, in (3) the reagent that evolves the oxygen also absorbs the carbonic acid.

Particulars of some forms are as follows :—

Apparatus.	Weight.	Oxygen Capacity.
	Lbs.	Cubic Feet.
Pneumatogen (Type II.)	14¼	5·8
Draeger	36–39	8·9
Shamrock	36	9·7
Fleuss	31	8·0
Weg	About 30	5·3
Proto	37	8·5
Meco	39½	8·5
Salvus	16	3·0
Aerolith	22	?
Aerophor	30	?

It is estimated that 120 cubic inches of oxygen per min. is ample for the severest exercise; a man at rest requires about 15 cubic inches, and climbing hills 90 cubic inches per min. The Aerolith uses liquid air containing about two parts of oxygen to one of nitrogen; it is stated that one gallon is sufficient for three hours' work.

The Aerophor holds 10 lbs. of liquid air, equal to about 125 cubic feet.

The following has been found to be a man's average consumption of oxygen per minute, gas dry, at N.T.P.

Rate of doing Work.	Breathing.			
	Air.		Oxygen.	
	Litres.	Cub. in.	Litres.	Cub. in.
At rest	0·36	22	0·32	19·5
3,000 ft.-lbs. per min.	1·12	68·3	0·97	59·2
6,000 " "	1·74	106·2	1·54	95
9,000 " "	2·33	142·2	2·16	131·8

The most economical rate of walking when travelling a flat road and wearing a rescue apparatus—*i.e.* the rate at which a maximum distance can be covered for a given supply of oxygen—is about 2½ miles per hour.

('*Second Report of the Mine Rescue Research Committee of the Department of Scientific and Industrial Research.*')

When the wet-bulb temperature is much above 80°F., a man cannot remain long at work; he can stand a wet-bulb temperature of 120°F. for about five minutes. (*J. S. Haldane.*)

To Detect Carbon Monoxide in the Air.—A Technical Paper (No. 11) of the United States Bureau of Mines suggests the following simple test capable of detecting as little as 0·03 per cent. of carbon monoxide in the air. One or two drops of blood from a pricked finger are diluted with water until this assumes a buff-yellow colour. Some of this discoloured water is placed in two 100 cubic centimetre test tubes, and one of the tubes is to be taken into the mine, where one-half is to be poured away at the place where the air is to be tested, the mine air taking the place of the water poured away. The tube is then to be corked, taken to the surface, and to be shaken for about ten minutes. If the air in the test tube contains CO, the pink colour of the liquid will indicate the presence of hæmoglobin on comparing the tube with the other test tube filled with the normal fluid. Mr. Ivor Graham has shown that carbon monoxide is a normal constituent of the air of coal mines over 1,500 ft. deep, being produced by the slow oxidation of carbonaceous material at the coal face, in the roads and in the goaf; it is usually under 0·005 per cent., but in a few cases 0·012 per cent. has been found.

('*Trans. Inst. Min. Eng.*,' Sept. 1920.)

Spontaneous Combustion.

Work in the Doncaster Coal Owners' Laboratory has shown that the liability of a coal to spontaneous combustion in the goaf depends, other things being equal, upon its capacity for absorbing oxygen. It appears that a coal, 100 grammes of which, ground to 200 mesh, absorbs less than 200 c.c. in 96 hours at 30°C., is only liable to gob fires when the working conditions especially favour the latter. Coals liable to fire absorb over 300 c.c. in the same time. Presence of pyrites, especially when finely divided, increases the liability to spontaneous combustion.

Fire Extinction.

Investigations have been made recently into the scientific side of mud-jet working for fire extinction in colliery workings, and it has been decided that the material of the mud, some of which should be of a lime and some of a clay character, should consist of sifted earth of 5 mm.

esh, boiler ash, dust from the cleaning of blast-furnace gas, and even combustible material, such s the refuse of coal washing, can be added to make up bulk without any risk should nothing ore suitable be at hand. In the majority of instances the mud tank can be so placed as to operate y gravity, but steam or compressed air pressure can be used. It has been found that if a tank placed at a height of, say, 15 yards, it will force the mud a horizontal distance of 150 yards, ven allowing for fairly sharp bends in the conducting pipes.

Electric Signalling in Coal Mines.

A circular issued by the Home Office points out that while there is no difficulty in constructing ells and relays that will comply with the requirements laid down—i.e. which will not 'spark'—ost of those in ordinary use in coal mines do not comply with the provision of General Regu-tion 132; and it states that in mines to which this regulation applies steps must be taken ithout delay to bring into compliance with the regulation any existing installations which o not already comply, while no new apparatus must be installed except such as does strictly omply. The fact is emphasised in the report that with the usual type of bell and magnitude f battery at present employed, nearly every break-flash that occurs when the bare signal wires re separated would ignite a mixture of firedamp and air containing between 7·5 and 9·5 per cent. f methane, were such a mixture to surround the wires at the time.

Relays, although not requiring for their action so great a battery power as bells, have wing to their higher inductance a lower 'igniting-current' at which the break-flash on the ignal wires becomes dangerous. At the present time, with few exceptions, the battery power sed on relays is in excess of that sufficient to give a dangerous break-flash at the signal wires. he commonest kinds of relays are dangerous when used with a battery of more than four wet eclanché cells, or with any current in excess of the current given by such a battery.

The report shows in detail how the bare wire system of electrical signalling as commonly mployed can be rendered quite secure from any danger of the ignition of inflammable gases y the break-flash at the signal wires or at the contacts of the signalling instruments.

In order to secure a safe bare-wire signalling system it is necessary in the first place that he battery power employed on any one circuit should be limited, and, in the second place, that he signalling instrument, whether bell or relay, should comply with certain requirements set ut in the report.

The maximum pressure allowed by the General Regulation (No. 134 (a)) for a signalling ircuit is 25 volts, and from the point of view of safety a pressure of 25 volts is not excessive, rovided that, as is usual, wet Leclanché cells (quart size) are employed.

Systems in which the battery used consists of dry primary cells or secondary cells, or in which continuous or alternating current generators are employed, can be rendered safe if, in ddition to the use of anti-sparking devices, sufficient non-inductive resistances are permanently nstalled in the circuit.

Both bells and relays should have flame-tight covers (preferably locked), and should be so onstructed and maintained that when included in a circuit with a battery at 25 volts the break-lash produced, when bare signal wires are separated after giving a signal, is incapable of gniting an 8 per cent. methane air mixture.

ORE DRESSING AND COAL WASHING.

(For details see 'The Dressing of Minerals,' by Henry Louis, from which the following is mainly bstracted.)

The operations included under the head of dressing comprise all the operations between the xtraction of the crude mineral from the mine and rendering it merchantable, thus forming a link etween the operations of the miner and the metallurgist. By common consent, gold milling is enerally looked upon as a dressing operation, though it is doubtful whether cyanidation should lso be included.

The various operations consist of :—

Hand picking or sorting.

Comminution (coarse breaking or crushing and fine breaking or grinding).

Sizing (preliminary or rough sizing and final or fine sizing).

Classifying.

Separation by differences of specific gravity, magnetism, electric conductivity, or surface ension.

Usually a more or less complicated series of operations is required, especially in the case of omplex ores, and these are usually indicated by means of flow sheets.

Let the weight of feed in any concentration process be A and its assay a per cent., the weight nd assay of concentrates be B and b and of tails C and c respectively, then the

$$\text{Enrichment ratio} = \frac{b}{a} = \frac{\%\ \text{Recovery}}{\%\ \text{Concentration}}.$$

$$\% \text{ Concentration} = \frac{100B}{A} = \frac{100(a-c)}{b-c}.$$

$$\% \text{ Recovery} = \frac{100b(a-c)}{a(b-c)} = \frac{B100b}{Aa}. \quad A = \frac{B(b-c)}{a-c}.$$

$$\% \text{ Efficiency of concentration} = 100\frac{B}{A}\left(\frac{b}{a} - \frac{100-b}{100-a}\right) = 100\frac{a-c}{b-c}\left(\frac{b}{a} - \frac{100-b}{100-a}\right) =$$

$$100\ \frac{\% \text{ Recovery} - \% \text{ Concentration}}{\% \text{ Waste in feed}}.$$

(*R. T. Hancock.*)

Sorting is performed either on floors or on picking belts or tables. An ordinary pickin belt may be of iron plates 4 ft. wide, 50 to 100 ft. long, travelling at 40 to 65 ft. per minute Pickers stand on both sides, 7 ft. to 15 ft. apart; each picker can treat 1–3 tons of coals pe hour.

Power required to drive, 2½ to 5 h.p. Upkeep, about 50*l.* per annum.

Rubber-covered canvas belts about 32 ins. wide are also used, and will carry 25 to 50 ton per hour at speeds of 30 to 60 ft. per minute.

Circular tables are 3 to 4 ft. wide, 10 ft. to 18 ft. in diameter, revolving with a peripheral spee of 40 to 60 ft. per minute, and can deal with 30 to 70 tons of mineral per hour.

Comminution.—Rough breaking is done by jaw breakers, either reciprocating like thos of the Blake, Dodge, etc., type, or gyrating like the Gates type. The former have been built t take pieces up to 5 ft. by 7 ft., requiring 300 h.p. to drive, and breaking 300 tons per hour. Smalle breakers usually break 1 ton per hour for a consumption of 2–3 h.p. The gyrating crusher i better suited to very large outputs, but cannot take such large pieces, and appears to be rathe more economical of power.

Fine Crushing.—Rolls are used for medium and fine crushing. Let r be the radius o the particle to be broken and d the radius of the particles in the crushed product (both con sidered as spheres); the minimum radius of the roll should be $> 25\ (r - d)$.

For fine crushing to about ⅛-in. mesh the following table shows the general practice :—

Rolls.		Revs. per minute.	Horse-power required.	Cwts. crushed per hour.
Diam.	Face.			
10½ ins.	10½ ins.	130	3	25
12½ ,,	10½ ,,	110	4½	45
16 ,,	10½ ,,	90	6½	65
21 ,,	10½ ,,	75	9½	100
27 ,,	11 ,,	45	12½	145
37 ,,	12 ,,	45	16	200

The peripheral speed should be greater the finer the product required; for grinding t 40 mesh the speed should be 1,000 ft. per minute.

In large plants three or four sets of rolls are placed in series so as gradually to reduce the or to the desired size. At Mount Morgan, such a plant consisted of eight sets of rolls in two serie of four, thus :—

26 ins. diam., 15 ins. face, set $\frac{3}{32}$ in. apart, 112 revs. per min.
26 ,, 15 ,, ,, $\frac{1}{16}$,, ,, ,,
30 ,, 16 ,, ,, $\frac{1}{16}$,, ,, ,,
30 ,, 16 ,, ,, in contact ,,

The total power consumption was 100 h.p. and the crushing capacity 125 tons per 24 hour crushed to 20 mesh (0·025 in.); the wear on the steel roll-shells was 0·108 lb. of steel per to of ore crushed.

Stamps.—The ordinary gravitation stamp is used more largely for gold milling than fo other purposes, but also for crushing tinstone, etc. The complete stamp consists of the head shoe, stem and tappet, the weight of which may be up to 1,500 lbs. The relative weights ar about 30, 17, 40, 13. It is lifted by a cam forming the involute of a circle; if h be the lift o the stamp, r the radius of the pitch circle of the involute, and a the angular motion of the cam during the lift, $h = \frac{\pi r a}{180}$. The speed is usually about 90 drops per minute.

If n be the number of drops per minute, h the drop in inches, s the number of stamps, and w the weight of a stamp in pounds, the power required is approximately $\frac{nhsw}{300{,}000}$. (For a more

exact formula see 'A Handbook of Gold Milling,' by H. Louis.) The average crushing capacity s 2–8 tons per 24 hours for a 1,000 lb. stamp. The Husband atmospheric stamp with two heads requires 35 h.p. to work it, and can crush 40 tons of hard tinstone per 24 hours down to 0·048 in.

Steam stamps are used mainly for crushing the copper-bearing rocks of the Lake Superior Mines, down to about ¼-in. mesh. One such stamp will crush 10 tons per hour, the efficiency being about 1·75 tons per i.h.p. per 24 hours.

Ball mills have been made both for dry and wet crushing. The Krupp mill is a dry-crushing mill; the No. 5 size, which is largely used, is 86 ins. diameter by 46 ins. length, makes 20–25 r.p.m., weighs 182 cwts., and a set of balls weighs 18 cwts. At Mount Morgan these mills require 13 h.p. and crush 22·7 tons per 24 hours to 20 mesh (0·025 in.). The balls wear at the rate of 0·725 lb. and the hunch plates at the rate of 0·681 lb. per ton of ore crushed.

Wet crushing ball mills are 60 ins. to 80 ins. in diameter and about 40 ins. long. A charge of balls for such a mill weighs about 2 tons; it is run at 25 to 30 r.p.m., takes from 25 to 35 h.p. to drive it, and will crush 25 to 100 tons down to 0·02 mesh per 24 hours; the water consumption is about 65 gallons per minute.

The tube mill is also used wet or dry, and is in effect an elongated ball mill, 3 ft. to 5 ft. in diameter and 13 ft. to 26 ft. long. A tube mill 4 ft. in diameter, 16 ft. 6 ins. long, crushed in Western Australia 38 tons of sand per 24 hours, 95 per cent. of the product being finer than 100 mesh, requiring 30 h.p. to drive it. Such mills are lined with silex, chilled iron, or hard steel bars, and are usually charged with flints. According to Mr. Davidson, the best number of r.p.m. $= 200 \div \sqrt{d}$, where d is the internal diameter in inches; the weight of flints in pounds should be $N \div 44$, where N is the internal capacity of the mill in cubic feet. Western Australian practice corresponds nearly to $N \div 60$.

The Marathon mill uses rods in place of balls; a mill 3 ft. diam., 7 ft. long, charged with 7,000 lbs. of rods ½ in. to 2 in. diam., running at 30 r.p.m., crushed 18 tons per hour with a consumption of 12·5 h.p., using 42 U.S.A. gallons of water per minute. The feed was below ½-in. mesh and the product was ground to $\frac{1}{1\cdot3}$-in. mesh, 14 per cent. being below $\frac{1}{400}$-in. mesh. The wear of the line plates was 0·14 lb. and of the rods 0·4 lb. per ton of feed.
(*Trans. Amer. Inst. Min. Eng.*, lv., p. 678; lvii., p. 355.)

The Hardinge tube mill has the form of two cones base to base. An 8 ft. Hardinge mill requires 50 h.p. to drive it, and requires about 10 h.p. hours per ton crushed to about 48 mesh.

An 8 ft. × 22 ft. mill crushed 200–250 tons per 24 hrs. using about 56 h.p., with a charge of 5 tons of Danish pebbles wearing at the rate of 2·16 lbs. per ton of feed; with steel balls instead of pebbles 360–400 tons were crushed per 24 hours.
(*Trans. Amer. Inst. Min. Eng.*, lv., p. 678.)

The Marcy mill is a short mill (5–6 ft.) with perforated diaphragm at the discharge end, from 2 ins. to 48 mesh. An 8 ft. by 6 ft. mill driven by a 225 h.p. motor crushes 550 tons per 24 hours at 24 r.p.m., carrying 30,000 lbs. chrome steel balls.
(*C. T. Van Winkle, Trans. Amer. Inst. Min. Eng.*, vol. lix. (1918), p. 227.)

The Huntingdon mill is made in three sizes, 3 ft. 6 ins., 5 ft. and 6 ft. diam.; No. 2 is most used; it weighs about 5 tons; consumes 12 h.p.; makes 60–70 r.p.m., and will crush about 10 tons per 24 hours to about 15 mesh.

The Arrastra is 10 to 20 ft. in diameter, has usually four dragstones, 6–8 cwts. in weight. At 6 to 12 r.p.m. a charge of 1 to 3 tons is ground in 2–3 hours.

The Chilian mill has 2–3 rollers, 4 to 6 ft. in diameter, takes up to 75 h.p., and crushes up to 150 tons per 24 hours.

Sizing.—For coarse screening fixed grizzlies or 'jigging' screens are used. For medium and fine screening mostly trommels, 8 ft. to 2 ft. in diameter by 12 ft. to 3 ft. long; the peripheral velocity is usually 50 to 200 ft. per minute. The slopes may vary from 5° to 14°, averaging about 7°. A set of seven trommels, 3 ft. diam., 5 ft. long, will size about 7 tons of ordinary crushed material per hour, and require up to 5 h.p. to drive it.

Classification.—This term applies to the separation into groups of equal falling particles The terminal velocity of a particle falling freely in water is approximately $V = 2{\cdot}6\sqrt{D(S-1)}$ where V is the velocity in metres per second, D the diameter in metres of the screen mesh through which the particle just passes, and S the density of the mineral. This velocity will be attained

after the particle has fallen a distance equal to $V^2 \div 4$ metres approximately. When V is less than 0·5 to 1, according to the substance, the law on which these formulas are based (friction ∝ velocity and viscosity negligible) no longer holds good. The particles fall more slowly, obey a different physical law, and are known as slimes, which are incapable of classification.

The minimum radius of a particle that obeys the above law of terminal velocity is

$$\sqrt{\frac{9\,\mu^2}{2\,g\,(s-1)}}\ \text{cm.};$$

where μ is the viscosity (0·0115) and g the acceleration of gravity (981), both in C.G.S. units, and s is the specific gravity of the particle.

Hence log radius in cm. $= \bar{3}\cdot92764 - \frac{1}{2}\log(s-1)$.

The following table is calculated from the above formula :—

Sp. gr.	Radius in mm.	Sp. gr.	Radius in mm.	Sp. gr.	Radius in mm.	Sp. gr.	Radius in mm.	Sp. gr.	Radius in mm.	Sp. gr.	Radius in mm.
1·2	0·1528	1·6	0·1004	2·0	0·08465	2·4	0·07567	3·5	0·06237	5·5	0·05128
1·3	0·1265	1·7	0·09534	2·1	0·08201	2·5	0·07395	4·0	0·05870	6·0	0·04950
1·4	0·1149	1·8	0·09118	2·2	0·07966	2·6	0·07238	4·5	0·05575		
1·5	0·1071	1·9	0·08768	2·3	0·07757	3·0	0·06719	5·0	0·05333		

Spitzkasten ; the first box should be 2 ft. wide for 10 cub. ft. pulp per minute, or 1–2 cwts. of solid matter ; boxes may increase in geometrical progression with factor of 1·5 ; length of first box about 6 ft., increasing by 3 ft. for each successive box.

Trough classifiers 10 to 20 ft. long, 1 ft. wide at narrow end, will treat 100 tons per 24 hours, with 100 cub. ft. of water per ton of crushed material.

Jigs.—The following represents the general modern practice :—

Diam. of particle .	0·25	0·50	0·75	1·00	1·25	1·50	1·75	2·00 ins.
Length of stroke .	0·4	1·2	1·55	1·8	2·0	2·15	2·3	2·4 "
No. of strokes per min.	200	160	145	130	125	125	125	125

CONTINENTAL JIGGING PRACTICE ON ORDINARY LEAD-ZINC ORES.

Three to five compartment jigs; screen surface 20" × 31·5".

Size of Particles.	Length of Stroke.	Strokes per Min.	Water per Cwt. treated.	Capacity per Sq. Ft. of Screen Area per Hour.
Inch.	Inch.		Gallons.	Cwt.
0·04	0·2	280	90	0·6
0·046 to 0·06	0·25	280	73	0·9
0·06 to 0·08	0·35	260	60	1·2
0·08 to 0·11	0·50	240	55	1·6
0·11 to 0·16	0·60	220	52	1·8
0·16 to 0·22	0·80	200	50	1·9
0·22 to 0·32	1·00	180	46	2·0
0·32 to 0·43	1·20	160	45	2·1
0·43 to 0·63	1·25	140	54	2·2
0·63 to 0·87	1·60	140	58	3·7
0·87 to 1·25	2·00	140	61	4·3

Jig screens of steel wire are liable to rapid corrosion when pyritic ores are being treated ; wire drawn from Ambrac (Cu75Ni20Zn5) has been recommended in such cases.

Round buddle; diam. 18 ft. to 25 ft. ; makes 5–10 r.p.m.. Capacity 1½–3 cub. ft. per min., carrying 28 to 56 lbs. material ; time of filling 3–10 hours.

Slime table; diam. 15 ft. to 25 ft. ; ¼–1 r.p.m. Pulp 1½–3 cub. ft. per min., carrying 4 to 7 lbs. per cub. ft. Clear water 1½–3 cub. ft. per min. Power required ½–1½ h.

Frue vanner; belt surface 4 ft. by 12 ft. ; fall 3 ins. to 6 ins. ; travel 6 ft. per min. ; strokes 200 per min. Capacity 0·25 to 0·5 cub. ft. pulp per min. ; 5 to 8 tons material 24 hours. Clear water ¼ of pulp. Power required ¼ h.p.

Lühring vanner; belt surface 3 ft. 6 ins. by 12 ft.; travel 8–12 ft. per min.; 160–180 strokes per min. Capacity 2½–7½ tons per 24 hours; clear water 1–2 cub. ft. per min. Power required ¾–1½ h.p.

Wilfley table; 16 ft. long, 6 ft. wide, tapering to 3 ft. Will take particles up to ¼ in. 240 strokes per min., ¾ in. long. Capacity 25 to 50 tons per 24 hours. Clear water 1 to 2 cub. ft. per min. Power required 1 h.p.

Coal Washing.*

Coal as it comes from the mine is first screened, usually over a 2 ins. to 2½ ins. screen; the oversize drops on to picking belts, where shale, dirty coal, etc., are picked out. The undersize is taken to a washery, especially when it is required for coke-making. A jigging screen with ¾-in. holes will screen about 1 ton per hour for each 0·75 sq. ft. of screening surface.

Coal is sometimes dry-cleaned in the Purdee spiral separator, in which it is allowed to slide down a spiral track, the clean coal falling over the outer edge, whilst the shale, etc., remains on the track.

When the separation of the clean coal from the accompanying shaly matter is easy, or when the products are not required in the highest possible state of purity, a simple form of washer may be used. Such is, e.g., the Elliott trough washer, capable of treating 5 to 10 tons of small coal per hour with a water consumption of 1,750 gallons per ton of coal washed. The Blackett washer is similar in principle, but the fixed trough with the moving dam-plates is replaced by a revolving drum within which is a spiral baffle-plate; it will treat 10 tons of small coal per hour, requiring 3,000 gallons of water in circulation per ton of coal washed. The Robinson washer works on the principle of a spitzkasten, with upward flow of water and a revolving stirrer; it can treat 15 to 20 tons of small coal per hour.

The purity of the washed coal is usually determined by floating it in solutions of known specific gravity; coal that floats in solutions of sp. gr. 1·35 to 1·45 is generally considered clean coal. The washing characteristics of a coal are best determined by constructing a washability curve or Henry curve. (See *Colliery Engineering*, 1925, p. 341.) The washability of coals is generally determined by plotting the proportions of the whole which float in solutions of definite specific gravities and the ash contents of these fractions as a curve, from the shape of which much valuable information as to the washing properties of the coal may be obtained. Most plants for such complete washing make use of jigs (bashes or boxes), and the coarser refuse is sometimes crushed and re-washed See flow-sheet No. I., p. 2623.

The Coppée Washery is typical of the more usual form of plant. The unwashed coal, say under 2 ins. to 3 ins., is sized before washing. The washing is carried out in two types of boxes, viz.: (*a*) Small coal feldspar boxes, which treat all the coal below ½ in.; (*b*) nut coal type of box, which treats the various sizes below 3 ins. and above ½ in. These sizes vary according to local conditions and the requirements of the market. The nut washers are 8 ft. deep, and the sieves are 5 ft. long and 3 ft. to 5 ft. wide, each washer treating 2·5 to 3·5 tons per hour per foot of width of screen. The more important data affecting the operations of nut washers are shown in the following table:—

Size of Nuts.	Depth of Layer of Shale on Sieve.	Length of Stroke.	No. of Strokes per Minute.	Mesh of Sieve.
½ in. to ¼ in.	2½ ins.	2½ ins.	80	$\frac{1}{10}$ in.
¼ " " 1 "	3 "	3 "	75	$\frac{2}{10}$ "
1 " " 2 ins.	3½ "	3½ "	70	¼ "
2 ins. " 3½ "	4½ "	4¾ "	65	$\frac{3}{10}$ "
3½ " " 5 "	5½ "	6¼ "	60	$\frac{5}{10}$ "

The Feldspar Washer is built in two compartments, each 4 ft. long, making a total length of 8 ft. by 2 ft. 6 ins. wide, the box being 5 ft. deep; such a washer can wash 7 to 10 tons of small coal per hour up to ½ in. in size. The following are the leading data:—

	1st Compartment.	2nd Compartment.
Thickness of layer of feldspar	2½ ins.	2½ ins.
" " " shale	$\frac{2}{10}$ in.	$\frac{2}{10}$ in.
Size of pieces of feldspar	$\frac{8}{10}$ in. to 1 in.	$\frac{8}{10}$ in. to $\frac{8}{10}$ in.
Length of stroke	0·55 in.	0·47 in.
No. of strokes per minute	165	165
Mesh of screen	0·55 in.	0·47 in.

* See 'The Preparation of Coal for the Market,' by H. Louis.

A plant to wash 100 tons per hour, 50 per cent. on nut washers and 50 per cent. on feldspa washers, would require four of the former, 4 ft. wide, and six of the latter. Such a plant woul require in circulation about 135,000 gallons of water, and make-up water amounting to betwee 2,800 and 3,500 gallons per hour.

When the refuse from the nut washers contains sufficient intergrown coal to be worth treating it is crushed, generally in a disintegrator, and the crushed material is re-washed on feldspa washers.

A coal washery may require from 1·5 to 3·5 h.p. for each ton of unwashed coal treated pe hour, varying with (*a*) the total output of the washery (a large washery requiring a relatively smaller h.p. per ton); (*b*) the quantity of interstratified coal, and whether the larger size i crushed and washed together with the smaller size, or whether the smaller size only is re-washed (*c*) the type and capacity of draining and storage bunkers, and whether apparatus is installe for mixing the various products.

Messrs. Simon-Carves, Limited, build washeries on the so-called Baum principle, in whic washing precedes classification. The slack below about 2 ins. is delivered to a bash having a area of about 0·8 sq. ft. per ton per hour; the washed coal then passes to a screen of abou $\frac{3}{8}$-in. mesh; the over-size is clean coal, and the under-size goes to a second bash having an are of about 1 sq. ft. per ton of coal per hour, the product being clean coal and refuse. The dir produced in the first washing can be further crushed and washed over again if necessary. A plant to treat 100 tons of slack per hour would, therefore, require a first bash with an area o 80 sq. ft., and a second bash with an area of $\frac{1}{4}$100 sq. ft.; the water in circulation would be abou 130,000 gallons per hour, and the make-up water required about 2,500 gallons.

The rhéolaveur consists of a series of troughs of steel, cement or wood, sometimes lined wit tiles, fitted with a series of pockets with adjustable discharges and, for the coarser sizes of coal, wit upward water flows. These are arranged so as to discharge clean coal, refuse or middlings for re washing as may be required. The plant is relatively cheap, compact and efficient and can treat a sizes from 4 in. to slurry. No general figures can be given as the plant has to be specially designed for each case. It is largely used in Belgium, and altogether about 60 million tons c coal a year are treated by it.

At Grassmoor Colliery a rhéolaveur plant treats 100 tons per hour 0-1 in. in two sizes, 40 ton 0-$\frac{3}{8}$ in., 60 tons $\frac{3}{8}$-1 in., absorbs 105 h.p., uses 140,000 gals. water in circulation.

(*A. Audry, Proc. So. Wales Inst. Eng.*, vol. xli., p. 567.)

In the United States small coal is being largely washed on shaking tables of the Wilfley type such a table will treat 5 to 8 tons per hour of coal under $\frac{3}{8}$-in. mesh, requiring about 1 h.p.

The flotation process has been applied to washing fine coal. (See *Trans. Inst. Min. Eng.* lxvii. p. 374.) It is being extensively used in Spanish collieries.

The Chance process employs a separating cone worked with a sludge consisting of sand an water; it is said to give excellent results on Anthracite, and is used in the U.S.A. (See *Tran Amer. Inst. Min. Met. Eng.*, vol. lxx. p. 740.)

The American Coal Cleaning Corporation's machine consists of a shaking table with riffle and a porous deck through which a current of air ascends on the principle of the Sutton-Steel table; this cleans dry coal and the finished product contains under 2 per cent. of extrinsic ash Over 10,000,000 tons of coal were cleaned in this way this year in the U.S.A. (See *Trans. Amer Inst. Min. Met. Eng.*, vol. lxx. p. 758.)

The largest American plant is the McComas plant at Crane Creek Mines, W. Virginia, treatin 225 tons per hour.

This table, known in England as the Birtley S.J. table, is used in a dry-cleaning plan erected at Wardley Colliery, Co. Durham. It treats coal under 2½ ins. and consists of six S.J tables with dust aspirators and bag house. Its capacity is 125 tons per hour, and it clean efficiently to within 2 per cent. of the intrinsic ash, there being under 1 per cent. of free coal i the refuse. A new type of dry-cleaning table, known as the Y table, having double the capacit of the S.J. table, and requiring less close sizing, has recently been introduced. Dust ma advantageously be removed from coal before the latter is washed, and treated separately b dry-cleaning in combination with a washery.

Dry-cleaning plants have been erected at Altham (Lancs) and Snowdon (Kent) and others ar being completed at Horden (Durham) and Thorne (Yorks); the last named is to treat 250-30 tons per hour.

The dry-cleaning system is fully described by K. C. Appleyard, *Trans. Inst. M.E.*, vol. lxxiii 1927, p. 404.

Dust is now often removed from coal that is not naturally too wet before it is cleaned by washin or dry-cleaning; it may be screened off by fine vibrating screens or may be taken out by an a current either on the screens or on the dry cleaning tables or else in a dust extractor; the dust collected by cyclones and bag-houses and is often used for dust-firing. Wedge wire is often used fo the fine screens.

Vibrating screens have a tightly stretched screening surface kept in rapid vibration and set at tolerably steep angle; the Hummer, Hayle, Overstrom, etc., screens differ mainly in the mechanism by which the vibration is produced.

For a good comparison of different methods of coal-cleaning see paper by Wheeler and Chapma in report of the Coal-Cleaning Conference at Edinburgh, July, 1927, pub. by Soc. Chem. Ind.

Mr. Norman Kemp has applied X-ray analysis to the products of the coal washery.

(*Trans. Inst. Min. Eng.*, vol. lxvii. p. 59.)

Magnetic Separation.

Maxima of magnetic susceptibility of minerals by volume in C.G.S.

Common non-ferrous minerals, e.g. mica, quartz, felspar, calcite, have susceptibilities < ·000001. 'Strongly' magnetic minerals have susceptibilities > 0·001. 'Feebly' magnetic minerals between 0·001 and 0·0001. (*After Prof. Ernest Wilson.*)

Magnetic separators: (1) For minerals of high magnetic susceptibility:—

Dry working, e.g. Wenström: drum 30 ins. diam., 24 ins. face. Capacity 5–7 tons per hour; will take lumps up to 7 lbs.; 30 r.p.m. Current 15 amperes at 120 volts.

Wet working, e.g. Gröndal: 24 ins. wide, 24 ins. diam., 100 r.p.m. Capacity up to 5 tons per hour. Current 10 amperes at 110 volts.

(2) For minerals of low magnetic susceptibility:—

Dry working, e.g. Rowand-Wetherill. Belt 18 ins. wide, three electro-magnets taking respectively 5, 15, and 30 amperes at 110 volts. Capacity, 0·25 to 1 ton per hour.

Wet working, e.g. Ulrich.

The Rapid Magnetting Machine Co., Ltd., Magnetic Separators.

(*The Rapid Magnetting Machine Co., Ltd., Birmingham.*)

When choosing a magnetic separator the greatest possible care should be exercised. The best method, which is, without exception, adopted by mineral mining concerns, is to send a reasonable size *normal* sample of the material to be treated, accompanied by information likely to be useful, as, for instance, the quantity to be treated per hour, voltage of current (D.C.) available, whether to be self-contained with feed attachment, space available, etc., etc., and inquirers should insist on the magnetic products being returned for examination for cleanliness.

Specification should be compared with specification, even after material has been tested, as a machine efficient as regards the actual extraction may be of such unsuitable design as to cause a constant loss of material being treated; and, where iron is to be removed as an impurity, guarantees of *efficient* output should also be obtained.

For feebly magnetic minerals the magnetic separators have to be of a special type. For such minerals the 'Rapid' (Thompson-Davies) Patent Ore Separator (dry-working) machine has been designed; this machine is 4 pole, 3 disc, 15-in. belt; the maximum current on each pole is 2½ amps. at 110 volts capacity. The machine will deal with about 3 tons of wolfram-tin per day, monazite sands 5 tons per day, but the capacity varies according to the characteristics of the ore.

Flotation Processes.

These may be classified as follows:—

I. *Film Flotation*, utilising differences of surface tension on particles at an air-water interface—e.g. De Bavay, Macquisten processes.

II. *Oil Flotation*, utilising differences of surface tension in an oil-water medium where the particles are buoyed up by oil—e.g. First Elmore process.

III. *Adhesive Processes*, utilising differences of surface tension between particles and oil or grease, causing differential adhesion to oiled or greased surfaces—e.g. Murex, Cattermole, greased-plate processes.

IV. *Froth Flotation*, utilising differences of surface tension at gas-water interfaces, wher the particles are buoyed up by bubbles of gas :—

(*a*) Where the bubbles are produced by chemical action—e.g. Potter, Delprat processes.
(*b*) Where the bubbles are produced by releasing the air dissolved in water—e.g. Elmor vacuum process.
(*c*) Where the bubbles are produced by mechanical means—e.g. Minerals Separation, Callow Janey, K. & K. (Kraut & Kolberg), Rork processes.

(See also 'Froth Flotation : its Commercial Application and its Influence on Modern Con centration and Smelting Practice,' Walter Broadbridge, *Bull. Inst. M. M.*, January 1920.)

COSTS OF FLOTATION MACHINES.

Tons capacity for 24 hours.	First Cost per ton of daily capacity.		Operating Costs per ton daily capacity.	
	Mechanical Agitation.	Pneumatic Agitation.	Mechanical Agitation.	Pneumatic Agitation.
25	$30–50	$25–40	$0·20–0·75	—
50	25–45	12–20	—	$0·20–0·75
100	20–40	8–12	0·35	0·35
250	15–35	6– 8	0·28	—
1,000	12–25	4– 6	0·17	0·17

Reagents used :— (*Ralston.*)

Gangue modifying :—Acids, alkalies, silicates, carbonates, and other salts.
Froth producing :—Soluble oils, essential oils, cresylic acid, amyl alcohol, etc.
Froth stabilising :—Insoluble oils, petroleum, etc.

Surface Tension of Liquids against Air.

	Dynes per sq. cm.			Dynes per sq. cm.
Water (at 0° C.)	75·8	Water with 0·14 per cent. cresol	(at 23° C.)	71·5
Water (,, 20° C.)	75·1			
Phenol (,, 41° C.)	37·0	Water with 0·14 per cent. amyl alcohol	(,, 23° C.)	68·4
Cresol	34·8			
Olive oil	32·0	Water with 0·134 per cent. saponine	(,, 23° C.)	48·7
Petroleum	27·7			
Turpentine	25·6	Water with eucalyptus 'solute'	(,, 20° C.)	44·6

Dilute sulphuric acid reduces the contact angle and hysteresis range of that angle far mo for quartz, silicates, and oxides than it does for metallic sulphides; oiling the latter greatl increases the contact angle and the hysteresis range.

(*H. L. Sulman*, 'A Contribution to the Study of Flotation,' *Bull. Inst. Min. Met.*, November 1919.)

The Inspiration Consolidated Copper Company's plant at Miami, Arizona, treats 15,000 tons i 24 hours. The ore contains 1¾ per cent. of copper, mainly in finely disseminated sulphide Flotation reagents used, 1¾ lbs. per ton of ore. Recovery, 85 per cent. of total copper, 90 per cen of copper present as sulphide ; concentrates contain 20 per cent. of copper.

(*Trans. Amer. Inst. Min. Eng.*, lv., 1916, p. 576.)

Selective flotation is very largely employed for the treatment of lead-zinc ores in th Western States and in Mexico.

Finely-ground coal may be froth-floated from shale, using 1 lb. of cresol and ½ lb. of paraffi per ton of coaly shale ; the latter contains about 65 per cent. of ash, the clean coal about 8 per cen

ELECTROSTATIC SEPARATION is used in some special cases—e.g. for concentrating ros blende, molybdenite, and graphite (Blake-Marsden and Huff processes).

DRY SEPARATORS, using currents of air instead of water, are used under exceptional condition

FLOW SHEETS.

GOLD MILLING.

With the improvements in the cyanide practice and also with the exhaustion of the rich free milling surface ores of various camps, which rendered such improvements necessary, have come changes in the process of treating gold ores. Instead of the simple Californian practice of crushing by 900 lb. stamps to about 40 mesh, amalgamating either in or outside the battery, concentrating the sulphides on vanners or shaking tables, chlorinating the concentrates, and sometimes treating the tailings by cyanidation, the 'all-sliming' process has come into force.

As practised on the Rand, the ore is screened through grizzlies with bars 2¾ ins. apart, the oversize going to a sorting belt, thence to a crusher. The ore passes into a feeder, thence to stamps weighing 2,000 lbs. per head, where it is crushed to pass a 10-mesh discharge screen. The pulp is classified in cones and the coarse product delivered to tube mills where it is slimed. The product of the tube mills, together with the overflow from the classifying cones, is delivered to the amalgamating tables. From the tables it is again classified, the sands being cyanided direct and the slimes treated by air agitation, then filter-pressed or vacuum-filtered.

The most vital changes from the old practice to the new have been: the use of the heavy gravity stamp merely as a preliminary coarse crusher for the tube mills; the adoption of the tube mills for fine grinding and the employment of the tall, air-agitation tanks and of filters.

The practice is modified in each district, the modification depending largely upon the nature of the ore. In some camps silver ores are being successfully treated by fine crushing and cyaniding

CYANIDE PROCESS.

This process may be conducted in a number of different methods, which may be classified as follows:—

I. Coarse crushing and direct cyanidation (exceptional).

II. Fine crushing with:—

A. Simultaneous cyanidation.

B. Subsequent cyanidation without classification.

C. Subsequent cyanidation, preceded by classification into (*a*) sand, (*b*) slime.

(*a*) Sand cyanidation, generally by percolation.

(*b*) Slime cyanidation, performed by

1. Decantation.
2. Agitation (mechanical or pneumatic) and filtration.
3. Direct cyanidation in filters.

D. All sliming methods with simultaneous or subsequent filtration.

(*H. Louis*, '*Handbook of Metallurgy*,' i. p. 1031, 3rd edn., Schnabel and Louis.)

Filtration methods may be classified as under:—

I. Suction filters, divided into:—

(*a*) Filters forming a thin cake, continuous acting.
(*b*) Filters forming a thick cake, intermittent.

II. Pressure filters, divided into:—

(*c*) Ordinary filter presses.
(*d*) Sluicing filter presses.
(*e*) Filtering chambers or cylinders.

III. Centrifugal filters.

(*S. J. Young*, '*Trans. Amer. Inst. M.E.*,' xlii., 1911, p. 752.)

Precipitation is performed by zinc shavings, zinc-lead shavings, zinc dust, aluminium electrolysis.

An average cyanide may be roughly estimated to cost complete $1,000 per ton treated per day in the Western States. An average cost of cyaniding, including crushing is thus about $1.50 per ton, but varies within very wide limits.

Stamps.

The duty of stamps depends upon the nature of the ore, the weight of the stamp, its speed and drop, the size of the aperture of discharge screen, and the height of the discharge, The following table gives the duty per stamp in various districts :—

DUTY OF STAMPS.

Mine or District.	Weight of Stamp.	Drop in Inches	Number of drops per Min.	Screen Aperture.	Discharge in Inches.	Tons Crushed per head per 24 Hrs.	Remarks.
California . .	900 lbs.	7	90	900 per sq. in.	4	3	Gold Quartz
Melones, Cal. .	1,000 ,,	7	104	20 mesh	—	4·41	
Tonopah Mill, U.S.A.	1,050 ,,	6½	104	slot ·04 in. wide	2½	5·09	Gold and Silver
Montana-Tonopah, U.S.A.	1,050	7	100	20 mesh	3	3·3	Gold and Silver
Tonopah Belmont, U.S.A.	1,050 ,,	6	104	24 mesh	—	3·7	,,
Goldfield, U.S.A..	1,050 ,,	7	108	12 mesh	—	6	,,
Komata Reefs Mine	1,030 ,,	6½	100	4½ holes per in.	4	5	Gold
Luipaards Vlei Rand	1,629 ,,	8½	98·6	200 holes per sq. in.	4	9·6	,,
Simmer & Jack East	1,550 ,,	8	96	200 holes per sq. in.	3½	8·3	,,
Waihi Grand Junction	1,110 ,,	7	105	5 to 10 mesh	1½	7·6	,,
Oroya Brownhill.	1,100 ,,	7¾	108	10 mesh	2	6·48	,,
Ivanhoe . .	1,192 ,,	7½	104	225 mesh	2	5½	,,
Gt. Fingall . .	1,150 ,,	8	106	12 mesh	3	7	,,
Mysore Gold Mine, Mysore, India	1,150 ,,	7·5	96	1,200, 625 and 400 per sq. in.	3	3·63	,,

It is claimed that the new 2,000 lb. stamps of the Goldfield (S.A.) are capable of crushing 6 tons of ore per stamp per 24 hours by introducing an elimination screen to 'bypass' the fine material from the rock bins direct to the tube mill and using screens with aperture of ·284 inch.

Amount of water varies on the Rand, from 5 to 10 tons of battery water to one of ore, depending upon the duty. In Western Australia the amount of water required is 4 to 8 gallons of water per stamp per minute.

Power per stamp.—The 2,000 lb. stamp requires 5 h.p. per stamp. In Nevada, for 1,250 lb. stamp 3·5 h.p. per stamp is used. At the Goldfield Con. in Nevada with 140 stamps, fine grinding and cyaniding, 1,500 h.p. is supplied to the mill or 1·73 h.p. per ton of ore milled.

COST OF EQUIPMENT OF GOLD MILLS.

The following is the comparative cost of gold mills, including all machinery and buildings :—

Mill.	Number of Stamps.	Cost of Machinery and Plant.	Cost per Stamp.
Rand Mill	200	£334,000	£1,670
New Kleinfontein	200	420,480	2,102
Wit Deep	200	346,210	1,731
Robinson Central Deep . .	100 and Tube Mill	234,013	2,340
Great Fingall	,,	193,745	1,937
El Oro	,,	160,000	1,600

In Nevada, the cost of complete plants doing fine grinding and slimes filtering is 1,400*l.* a stamp.

Tube Mills

are used as secondary crushers following the stamps. On the Rand they are most efficient when fed with ore that has been crushed through a screen the apertures of which are ·27 in. or say ¼ in. They are here 25 ft. in length by 5½ ft. in diameter, and one tube mill crushes the product of 10 stamps. Each tube mill requires 100 h.p. to drive it. In New Zealand tube mills are 16 ft. by 4 ft. revolving at 29 r.p.m., and driven by 25 h.p. motor. The feed is 1½ parts of water by weight to 1 part of ore. In 22 months a tube mill ground 28,500 tons of hard quartz, 50 per cent. of which passed through a 200-mesh screen.

At Pachuca 90 h.p. is used for a 5 ft. 6 ins. by 22 ft. tube mill. Output 140 tons per day through a 60-mesh screen.

At Waihi Grand Junction tube mills 19 ft. 3 ins. long by 4 ft. 8 ins. diameter require 42 h.p. Those 16 ft. 3 ins. long by 4 ft. 3 ins. diameter require 25 h.p. They consume 2·89 lbs. of flint pebbles per ton of ore crushed at stamps. They are run at 27 r.p.m.

Chilian Mills.

Chilian mills are employed either for crushing preliminary to amalgamation, in which case the gold is partly amalgamated in the mill itself, or they are used in lieu of the tube mill as fine grinders following the stamps.

For crushing ores for direct amalgamation the so-called slow speed Chilian mills are well adapted. Machines of this type are extensively employed in Russia and Siberia. They are expensive in first cost, but the power, labour, and repair costs are very low. Furthermore they are notable for their simplicity, requiring little close or skilled attention.

A slow speed Chilian mill was employed in California on hard close quartzose gold ore. It ran at 8 to 10 r.p.m. It had four runners each weighing 1,200 lbs. travelling on a steel die 3 ins. thick with 5 ins. face and 7 ft. outside diameter, 4½ tons of rock in a tank above and sustained by the axles giving additional crushing weight. Twenty tons of ore per 24 hours were crushed with a 4 in. discharge, and 88·1 per cent. extraction obtained 0·85 per cent. of the ore passed through a 100-mesh screen. One man per shift handled the mill. Cost of ore crushed 6*s.* per ton. Gasoline power was used consuming under heaviest load 2·17 gallons of distillate per hour. (*A. McLaren.*)

The standard type of Chilian mills used in Russia is 7 ft. to 10½ ft. in diameter with 2 runners 5½ to 6½ ft. in diameter, and from 7 to 12 ins. in width. The speed is 11 r.p.m. The discharge is 8 to 10 ins. Feed is about 1 in. and discharge screen slotted. The water is 6·5 to 10·1 times the ore in weight and duty is 16 to 24 tons per 24 hours. The power required is 7 to 12 h.p.

Rapid-running Chilian mills were used as fine grinders after the stamps in the Goldfield Consolidated mill in Nevada on fairly soft ore. There 140 stamps were in operation and six 6-ft. Chilian mills crushing from 4-mesh to 16-mesh were installed. These were operated at 32 r.p.m. Their capacity was 75 tons per 24 hours and the power required 35 h.p. each. The cost of crushing by these mills is given at 5*d.* per ton of ore milled. (*J. W. Hutchinson.*)

At Cripple Creek a 6-ft. Chilian mill running at 33 r.p.m. reduces 4 tons of ore per hour, 60 per cent. of which will pass a 150-mesh screen. The feed passed a ⅜-in. aperture.

Rolls.

Where a relatively small tonnage is to be crushed coarse, as for example when coarse concentration is employed or where the ore is porous and is cyanided coarse, it is the practice to use rolls. They are cheaper than gravity-stamps in first cost, repairs, labour, and power, and are not complicated by screens.

In South Dakota the ore, a hard, close-grained Cambrian quartzite, carrying from 5 dwts. to 7 dwts. per ton, is crushed by rolls. The ore is fed to two 16- by 36-in. rolls used as cracking rolls and two others of the same size are used as finishing rolls. The final product goes through a ⅛-in. mesh direct to the cyaniding vats. The rolls require 100 h.p. The milling and cyaniding cost is 2*s.* 2*d.* per ton and 14,800 tons of ore are treated monthly.

Ball Mills.

Krupp ball mills are used extensively in Kalgoorlie where 44 are at work. Size No. 5 will crush up to 45 tons of ore per day consuming 25 h.p. No. 8 will crush 90 tons per day requiring 50 to 60 h.p. About 45 per cent. of the product from a 25-mesh screen will pass 150-mesh. It is charged with 1 or 2 tons of steel balls and revolves from 21 to 25 times per minute. They work well on either wet or dry ores. The wear and tear of liners, hunch and scoop plates cost 4·64*d.* per ton milled.

Milling Costs.

The following are the milling costs of different stamp mills :—

Mill.	Stamps.	Tons Crushed Monthly.	Cost of Milling per ton.	Rate of Wages per day.	Remarks.
Tonopah, U.S.A.	100	15,000	12*s.*	13*s.*	Silver Gold ore
Goldfield Con., U.S.A.	140	29,500	9*s.*	13*s.*	
Ivanhoe	100	16,600	8*s.* 9*d.*	12*s.* to 14*s.*	Bromo-cyanide treatment of slimes
Oroya Brownhill	50	8,950	17*s.*	12*s.* to 14*s.*	
Gt. Boulder	—	14,800	12*s.* 4*d.*	12*s.* to 14*s.*	Dry crushing with Griffin mills. Roasting.
Melones, Cal.	100	12,000	1*s.* 1½*d.*	10*s.*	Cheap power, labour and supplies
New Unified (Rand)	—	10,000	1*s.* 4*d.*	—	Milling only
Simmer East	—	—	2*s.* 6*d.*	—	

On the Rand, cost of milling of those companies using tube mills varies from 4*s.* 10*d.* to 8*s.* 8*d.* per ton of ore.

In California, with free milling ores and cheap water power, milling costs average from 2*s.* to 4*s.* per ton. In Alaska, with large tonnages of soft, free milling ore treated daily and no cyaniding or fine grinding the costs are about 1*s.* per ton of ore.

Horse-Power per Ton of Ore Treated per Day.

Type of Mill.	Mesh.	Horse-power.
Stamps and vanners	20 to 40	0·75 to 1·0
Coarse concentration	10 to 20	0·5 to 0·8
Combination-stamp	16 to 30	1·5 to 1·75
Chloridising stamp (dry)	to 16	2·0 to 2·5
Chloridising stamp (wet)	to 40	4·0 to 4·5
Magnetic separator	—	0·25 to 0·5
Cyanidation (dry) roll-crushing	20 to 30	0·5 to 0·8
Cyanidation (wet), stamp crushing and sliming	to 80	0·75 to 1·5

(*J. A. Barr*, 'Testing for Metallurgical Processes.')

Standards Adopted by the Institution of Mining and Metallurgy.

1 oz. of fine gold = value 85*s.*
1 ton = 2,000 lbs. (avoirdupois).
1 miner's inch = a flow 1½ cubic ft. of water per minute
1 sluice head = „ 60 „ „
1 gallon of water = 10 lbs. at 34°.

Temperatures are to be expressed in centigrade.

Screen apertures and diameters of wire are equal, giving 25 per cent. screening area.

GOLD AND SILVER TABLES.

It is the practice of Continental and South American engineers to report the values of ore in grammes per metric ton. English engineers generally employ the method of quoting values in grs. and dwts., in some cases per long ton of 2,240 lbs., in others per short ton of 2,000 lbs.

TABLE for Conversion of Grammes per Metric Ton into Grains, etc., per Long and Short Ton.

Grammes per Metric Ton.	Per Short Ton.		Per Statute Ton.		Grammes per Metric Ton.	Per Short Ton.		Per Statute Ton.	
	Dwts.	Grs.	Dwts.	Grs.		Dwts.	Grs.	Dwts.	Grs.

Alluvial or Placer Mining.

Deposits of auriferous or tin-bearing alluvial gravels are termed placers, alluvial drifts, or more simply alluvials. They are classified as shallow or superficial and deep-lying, sometimes called deep leads. Deep leads are accumulations of gravel from extinct or ancient rivers. They are mostly capped by igneous flows, as in California and Victoria, though sometimes they may be buried under recent gravels or drift, as at Lightning Creek, B.C., and the Lena Goldfields in Siberia.

The methods of mining used to exploit deposits of this character resemble pillar and stall in some cases and long wall in others. In California the gravel beds can be attacked by means of adits which also serve as drains for the large amount of water present. When the topography of the ground permits adits being used, the cost of mining is low, as at the Hidden Treasure, California, where the costs average 4*s*. 6*d*. per cub. yd. of gravel washed. In the Deep Leads of Victoria, where the pumping charges were unusually large (eleven million gallons per day being raised from one mine), the total cost per cub. yd. was 12*s*. to 15*s*. At the Lena Goldfields the total cost is from 20*s*. to 30*s*. per cub. yd. of gravel washed.

Superficial Deposits.—All gravel under 60 feet in thickness may be termed shallow or superficial gravels. Surface gravels are worked by the following methods:—

Panning.—A miner can pan ½ cub. yard to 1 cub. yd. of gravel per 10-hour shift, depending on character of ground and nearness to water; 100 pans per day is a good day's work. Gravel in place is usually estimated at 3,000 lbs. per cub. yd., and the standard sheet iron pan 16 ins. diam. at top and 10¾ ins. diam. at bottom will hold 20 lbs.; 150 pans full will make a cub. yd. of dirt.

Rocker.—A man can rock ordinarily from 2 to 3 cubic yards of gravel per day, and save, in practical mining, 90 per cent. of the gold. In alluvial examinations the rocker plays a most important role, and is used in conjunction with the pan for determining the gold contents of any parcel of gravel. When used for this purpose, the design of the rocker differs slightly from that of the ordinary miner's rocker. A well-designed rocker, carefully employed, should save practically all the gold. The plans of most rockers, as published from time to time, are those of the ordinary mining rocker, which is too short, and set on too great a grade for use in saving fine gold. If much fine gold is present in the gravel, it will be advisable to use a strip of common Brussels carpet, laid along the floor of the rocker. This carpet is held in place by cleats and so can be easily removed in cleaning up.

Long Tom or short sluice can handle 3 to 10 cub. yds. of dirt per day, depending on the amount of water available and the character of the dirt.

Hand Sluicing.—Capacity of a sluice box depends upon the amount of water, grade of sluice, deposition of tailings, and character of gravel. No capacity can be given. Grade of sluice varies from 2 ins. to 21 ins. per box (12 ft.). An ordinary sluice box is made from 2-in. planks, and is 12 ins. wide by 12 ft. long.

Grade and Duty of Sluices.

Grade and Duty of Sluices.—The relation of actual width to the best ratio of quantity to width may not be very significant, but there is a notable increase in efficiency in passing from the smallest widths to the larger, and boxes less than 1 ft. wide are to be avoided, especially if the gravel is coarse. Treating 30- to 40-mesh sand on a 1 per cent. grade (say 1¼ in. per 12 ft. box), one sluice head of water requires a channel 2 ft. wide to enable it to attain maximum duty. On a 2 per cent. grade, half a sluice head requires 2 ft. of width, the quantity of water required for maximum duty with a fixed width diminishing with increasing grade, but at what rate there are insufficient data to determine. Apparently the best width required for constant quantity of water varies directly as the grade. Coarser material requires a greater depth of water, and for 4 to 6 mesh gravel on a 2 per cent. grade, 1 ft. of width per sluice head is indicated. Variations up to 50 per cent. in the water make little difference to its duty, consequently the actual position of the optimum is not easily determined. Naturally the capacity of the sluice itself is correspondingly varied, and the mode of transportation and the saving are doubtless affected in any case.

The rate at which duty varies with slope is the resultant of so many variables that no law can be stated for all cases. In the neighbourhood of the best conditions the Utah experiments support the approximate rule that duty (water, width, and material being constant) varies as the 1·75th power of the grade. A single experiment with natural gravel on low grades by the U.S. Geol. Survey gave the 1·84th power. (*R. T. Hancock.*)

Good modern practice provides about 1 ft. of sluice-box width for every 2 cub. yds. of average material treated per hour, and 3,000 gallons of water per cub. yd. treated on a grade of 6 ins. to 12 ft.

Besides the ordinary feeding of sluice box by means of hand shovelling, many modified methods of feeding and disposing of tailings are employed. In Russia and Siberia the favourite method in use is to transport the gravel to and from the sluice box (here greatly modified from the plain open sluice box) by the employment of horses and small carts. This is a most expensive system and the yardage treated is small. Other variations are: the use of wheel barrows, tramming by cars, handling gravel by means of derricks, digging gravels by means of steam shovels, and loading into cars or direct into sluice, feeding sluice by means of scrapers operated by horses or steam power (drag-line scrapers).

The methods of preventing accumulation of tailings are to deposit them in running water or to remove them by means of drags, belt or link elevators, or hydraulic elevators.

HYDRAULIC MINING.

Hydraulicing proper is the method of mining by which jets of water under high pressure are thrown against a gravel bank, thereby undermining the gravel which falls, and is carried by the current into the sluice. The necessary pressure is obtained either by natural means, *i.e.* by conveying the water from some source having a greater elevation than the working face, or by pumping directly into the supply pipe by powerful pumps. In the former case water is conveyed to the working by means of pipes, flumes or ditches. Ditches are generally most convenient and economical for conveying water for long distances, but sometimes the nature of the ground is such (either too porous or too rocky and difficult to excavate) that a flume becomes cheaper. When lumber is abundant wooden flumes are built, but in many cases, especially in the tropics, where wood rots rapidly, sheet steel flumes are preferable. Steel flume per foot, including rivets, angle iron, etc., ready for transport, costs from 4*s.* to 1*l.*; the sizes vary from a cross-section of 1·28 sq. ft. to 20·48 sq. ft. From the ditch or flume the water is fed through a strainer into a pressure box. From here, a pipe leads to the Y's, which in turn lead to the monitors or giants.

Monitors or Giants.

Monitors or Giants.—These are appliances consisting of a base for attachment to the pipe line and a long conical reducing piece, arranged with one or more joints so that it can be rotated in any direction horizontally and through a very wide angle vertically. The smaller or conical end is fitted with a nozzle butt to which different sizes of nozzles may be attached as circumstances may require. Modern giants are fitted with deflectors, attachments on the butts whereby the giant is turned or deflected by means of the force of the water itself. The high-pressure giants also have ball-bearing joints.

Nozzles from 2 ins. up to 10 ins. are used, working under heads or pressure from 100 up to 600 ft. or more.

The amount of gravel which can be washed down will depend upon its nature, upon the volume and pressure of the stream of water issuing from the nozzle, and is also dependent in no small degree upon the skill of the operator who handles the giant.

The following gives the approximate amount of gravel washed under various heads :—

Effective Head in Feet.	Size of Nozzle.	Flow in Cub. Ft. per Minute.	Approximate amount of Gravel in 24 hours in Cub. Yds.	Weight of Giant. Lbs.	Price of Double Jointed Ball Bearing Giant.
					£
100	2 ins.	104·88	160	120	28

400		5248	8,140		

(*Hendry.*)

Hydraulic Monitors and Pelton Wheel Jets.

J. J. Garrard (*Trans. I.M.M.* 1917) gives a table of discharges in cubic feet per minute for different sizes of nozzles and various heads derived from the formula : Delivery in cub. ft. per min. $= 3{\cdot}75\, d^2\sqrt[3]{P}$, where d = diameter of nozzle opening in ins. and P = gauge pressure in lbs. per sq. in., or effective head $\times 0{\cdot}4326$. An equivalent formula given by him is $2{\cdot}468\, d^2\sqrt[3]{h}$, where h = effective head in ft. The factor 2·468 allows for a nozzle contraction coefficient of 0·94, whereas Hendry's figures in the above table are based on the theoretical value 2·624, and make no such allowance.

Costs.

The costs per cub. yd. were at North Bloomfield 2·05*d.* per cub. yd. and at La Grange 3*d.*

In British Columbia one and a half million cub. yds. were mined and washed at a working cost of 0·97*d.*

In Northern California placer ground containing only 1·26*d.* per cub. yd. has been profitably worked. The amount of gravel washed was 1,251,399 cub. yds., yielding 6,330*l.* The profit obtained was 821*l.*

Hydraulic and other Elevators.

When a hydraulic mine possesses an insufficient slope of bed rock for moving material (the lightest grade permissible being 220 ft. to the mile) other methods of disposing of the gravel 'piped' must be employed. Where water under pressure is cheap and abundant the hydraulic elevators are employed. They are of the pipe type—either Hendry, Evans or Campbell and the Giant Elevator.

The pipe elevator operates on the principle of an injector. Water under pressure is discharged through a nozzle set within a steel jacket, creating a vacuum, and causing water and sand and gravel fed into intake to rise to a height corresponding to 10 per cent. of the head under which the water is applied.

Three sizes are made: 10-inch throat 3½–4½ inch nozzle, using 300 to 500 ins. of water; 12-inch throat 4½–5 inch nozzle, 500 to 750 ins. of water; 15-inch throat, 750 to 1,000 ins. They weigh about a ton and cost 250*l.*

In South Oregon, U.S.A., at the Weimer placer mine, two hydraulic elevators are employed to handle the gravels. One of them has a lift of 39 ft., and operating with a head of 330 ft., uses 11 cub. ft. of water per sec., besides taking all water from two No. 2 Giants. The second elevator has a lift of 9 ft., a head of 125, and uses 18 cub. ft. of water per sec. besides all the water from the first elevator. This makes a final discharge of 40 cub. ft. per sec.

Giant Elevators.

Besides undermining and cutting the gravel it has been discovered that gravel can be effectively 'driven' up a slope or incline to a raised line of sluices by means of the power of water under pressure. An elevator based on this principle is termed a 'stacker.'

In California a stacker was operated as follows: A chute was built sloping upwards at 30°. This was 4 ft. wide by 24 ft. long and constructed of 1½-inch planks. Riffles 2 ins. apart and with a drop of 2½ ins. between were laid across the bottom. These were covered by an iron grizzly. At the foot of this chute a 3-foot sump was dug in which was set up a hydraulic elevator with a 12-inch throat and worked by a 5-inch giant. This elevator, working under a 90-foot head, elevated to 16 ft. vertically the seepage, fine and water from two field-giants.

Twenty feet in front of the stacker was installed the 3-inch drive giant. Two 4-inch field-giants wash the gravel to the chute and the drive giant forces it up the stack, the fine material falling through the grizzly and down the riffles to the elevator, which raises it to the sluice-boxes.

The field-giants handled 600 cub. yds. per 24 hours, and the gravel could easily be raised to 25 ft. vertically by means of the drive giant. The cost of handling material exclusive of equipment was under 2½*d.* per cub. yd. (*S. S. Smith.*)

Ruble Elevator.

The Ruble elevator is constructed on the above principle, but it is more portable and does away with the hydraulic elevator. It is also self-contained, as the sluice-box is part of the machine.

In Idaho, U.S.A., this elevator has been tried with excellent results (*see* Porter, T.A.I.M.E., 1909, for a detailed description of this elevator). The following points are claimed to its merit: 1. It handles larger rocks with less water than other types of elevators. Handles boulders up to 1 ton in weight. 2. It dispenses with the boulder crew, either at the mine, ground, sluice-box or dump. 3. It saves the gold and the gold-saving department may be protected by lock and key. 4. The gravel is picked up in close proximity to the giants, the gold immediately extracted, and the boulders and other waste material dropped back on bedrock previously worked off, instead of being transported a long distance to the dump. It makes its own dump.

Mechanical Elevator.

In regions where water is neither cheap nor abundant, in handling gravel or tailings, resort must be made to some form of mechanical elevators. A mechanical elevator was erected some years ago on Bonanza Creek, Alaska. This was made of a frame of steel, 49 ft. high, mounted on wheels. The gravel was elevated by a bucket line of the close-connected type, 76 buckets in all, each with a capacity of 3 cub. ft. each. These discharged at a rate of 26 per min. directly into a sluice-box. The pit was drained by means of a 12-inch centrifugal pump, assisted by a hydraulic jet. The power was 200 h.p. in all, 35 for the bucket line and 165–175 for the pumps. The actual capacity per day was 1,500 yds. (*T. A. Rickard*). The first cost of this machine was high, and in actual running it proved costly in operation and repairs. Another machine of the same type, but employing a heavy dredge bucket, is being erected in Eastern Canada. No results of actual working are yet to hand.

Centrifugal Pumps.

Centrifugal Pumps as a means of elevating gravel and tailings have been extensively employed in Australia. It is claimed that with wood fuel at 7*s.* per ton of 50 cub. ft. and European rate of wages paid, to elevate tailings with pumps should not cost more than 2½*d.* per cub. yd. of solid. Thompson & Co., of Victoria, are the makers of gravel pumps suitable for this class of work. Their pumps vary in size from 3½ ins. to 16 ins. The capacity of solids per hour from 7 to 150 cub. yds. The indicated horse-power from 2½ to 583. The combined suction and delivery head from 10 feet to 100. An installation of this kind possesses the advantage of being cheaper to erect and easier to move than the belt or bucket type of elevators mentioned. However, where there is an undue amount of large stones present in the gravel, the latter type is preferable.

Pipe Lining.

Three rubber-lined pipes, each of 9 in. internal diameter and length of about 20 ft., have been in continuous operation on the discharge line from an 8-in. gravel pump at the Sungei Bari Mine, Malaya, for a period ranging from 18 months from the date of installation of the first pipe. These pipes have been subjected to a continuous flow of gravel, amounting to about 17,000 cub. yds. of solids per month, and a working pressure of about 17 lb. per sq. in. The three pipes, although differing somewhat in design, are all alike regarding the successful results of the rubber applied to them, there being little or no evidence of wear or abrasion on the rubber after this lengthy period of operation. The lining is of crepe rubber about ½ in. thick. The life of a lap-welded mild steel pipe ⅝ in. thick on the same line, with frequent turning to ensure even wear, does not amount to an average of seven months. ('*Mechanical World*,' Jan. 21, 1927.)

Dredging for Alluvial Minerals.

(Contributed by Harold E. Fletcher, A.I.N.A., M.I.Mar.E.).

The most important form of alluvial mining is dredging, for the recovery of gold, platinum, and tin. The greater part of the platinum recovered in Siberia and Russia is by dredging, and that of the tin in the Malay States. When all conditions requisite for successful working are present, when the ground has been properly proved* and a well-designed and effective dredge installed, then this type of mining is the safest and surest of all forms of mining investment.

Careful systematic boring is necessary to get true values. Dredging properties call for certain conditions, and unless these exist the success of the enterprise suffers. The conditions are :

(1) The presence of the mineral, which should be evenly distributed throughout the pay dirt.
(2) Sufficient ground to warrant the installation of at least one dredge.
(3) Soft bedrock, free from pinnacles.
(4) Absence of large boulders.
(5) Absence of permanently frozen ground.
(6) Absence of great amount of clay.
(7) Absence of heavy floods.
(8) Surface of an even contour, not too rough and broken.
(9) The ground should retain sufficient water to float dredge (50 miner's ins.), or available water supply from a river.
(10) The economic conditions, *i.e.* labour, transport, climate, vary inversely with amount of mineral in ground.

Broad flood plains or ancient lake gravels form more suitable dredging ground than does deposit situated in narrow rocky gulches. Frozen ground cannot be dredged without preliminary thawing. Dredging of gravels lying in rapid rivers is risky, as there is always danger of losing the dredge by sudden floods. Gravels from 10 to 80 ft. below water and 20 ft. above have been successfully dredged.

The modern dredge consists of a hull or pontoon of wood or steel, upon which is mounted the digging device, a bucket ladder capable of being raised and lowered, the washing plant comprising screen, tables or launders, the pump, of the centrifugal type for water supply to screen and tables, the stacker or elevator to dispose of the tailings well astern of the dredge, and the power plant. The buckets raise the ground and discharge into the revolving perforated screen, the fines pass through the perforations on to the tables, and the stones and large material pass through the screen to the tail chute and on to the tailings stacker. The dredge can cut its own passage. The cutting depth and manœuvring lines are worked by special multi-barrelled winches, controlled by one man, the winchman.

'Suction' dredges are used at times; they are only successful in light and free ground with level bedrock. The power required has been found to exceed that of the bucket dredge of equal output. With the suction dredge it has been found difficult to control the surges of water that sweep the tables when the spoil will not draw easily. This type of dredge has not given good results on tin in the Straits of Malay.

'Bucket' dredges are classified in two types, the New Zealand and the American; the latter has been evolved from the former to suit conditions existing in California and other parts. The principle is the same, but the American type is associated with heavier construction, larger buckets of the close-connected type instead of open, spuds (adjustable piles) instead of a headline, the raised pilot (or central control house), and other modifications. Both types have their advocates and both their utility.

The New Zealand type was associated with open-connected buckets, moderate power, simple engine for driving all units and light construction, but to-day this type is built of fairly large capacity and heavier construction. In its smaller sizes for lighter ground its first cost is in its favour, also for prospecting work or proving a dredging property; also where difficulties of transport prevent the use of the heavier type of dredge.

Transport.—Dredges are generally shipped in pieces for re-erection, the steel pontoons being riveted and launched at site. The heaviest parts to transport are the main engine castings, the boiler shell, the tumbler castings (mostly steel), crown wheel castings, winch barrels, screen ends, etc. The 'Tumblers' weigh from 15 cwts. in the small to 15 tons in the large sizes; boilers stripped, from 3 to 10 tons; watertube boilers, the heaviest part being the steam drum, from 7 to 60 cwts.

Hulls.—These have to be strongly designed to stand the stresses. Wood pontoons are not entirely satisfactory and generally have to be replaced during the life of the machinery; they suffer damage by ice in cold countries, and are difficult to build to stand stresses, and much heavier than steel.

Power.—Where wood and coal are plentiful, steam is cheapest. In Malay the Rawang coal (8,000 B.Th.U.) is used in water-tube boilers with chain grate stokers; steam pressure 160 lbs., and 100° superheat. Where oil is available at reasonable cost, it can be burnt under boiler or used in Diesel or semi-Diesel engines, and these have proved more economical than steam.

A gold dredge with 9 cu. ft. close-connected buckets is running in South America with semi-Diesel engines, also smaller dredges in Burma, etc. Full Diesel engines require the services of

* See *Alluvial Prospecting*, by C. Raeburn and H. B. Milner. 1927.

a specially skilled engineer. Producer gas plant and engines are used in Burma, Malay, Africa, etc., running on charcoal, driving direct or driving generators to supply current to the several motors. Where electric current is available and power can be transmitted to the dredge by cable at reasonable cost, and transformed on the dredge to the required voltage, it is in favour of low running costs, but it is generally accepted that it does not pay to build a special generating plant unless the ground will carry four or more dredges. Waterfall power to generate current is also being used.

The horse-power installed on gold and platinum dredges varies according to the capacity of bucket, dredging depth, etc. The distribution of power is generally as follows:

Bucket chain . .	33% of total power.	Screen . . .	10% of total power.
Water-pump . .	30% ,, ,,	Elevator . . .	12% ,, ,,
Winch . . .	15% ,, ,,		

On tin dredges, where larger water supply is necessary and higher water pressure, the pump power proportion is larger. On large dredges a separate winch is often fitted to deal with the bucket ladder.

Gold Dredges.

Larger types of American design are used in America, Siberia, etc., in addition to the open-connected type. Gold is saved on tables covered with cocoanut matting and expanded metal; the gold by reason of its heavy specific gravity settles in the mats, the dirt being washed down the tables overboard, the mats being taken up at periods and washed. With properly designed tables and adjustable water supply, quite fine gold can be saved. Platinum is easier to save owing to its heavier specific gravity.

Tin Dredges.

Of recent years these have increased in size considerably. The difficulty is not in raising the ground, but in treating it efficiently; the tables require to be of large area and the water supply larger than for gold dredging. Tables or 'launders' are generally from 3 to 4 ft. wide and up to 80 and 100 ft. long, wood riffles are fitted, and the wash agitated gently by hand-raking or mechanical means to allow the tin to sink through the wash and settle on the bottom of the launders. Owing to the large area of the tables the pontoons are of larger dimensions than for gold dredges; tables up to 7,000 to 8,000 sq. ft. area in two tiers are in use. Owing to the difficulty of carrying such tables, some of the latest dredges have been designed with jigs and classifiers, or a combination of riffles, launders, jigs, and classifiers, which will allow of better treatment and the saving of finer tin. The use of jigs allows of better saving adjustment. With skilled attention, up to 92 per cent. of the boring values have been obtained. Clay in the ground in both gold and tin dredging presents great difficulty to the dredge designer, and to break it up and release the values it contains call for special arrangements, such as puddlers, high water pressure, etc.

The design for tin dredges is tending towards the American type in regard to the design of the driving gear, buckets, tumblers, winches, etc. The latest dredges have close-connected buckets of cast manganese steel and nickel-chrome steel pins, cast manganese tumblers, etc.

There has been a vast amount of capital put into tin dredging in the Malay States and Siam, the number of dredging plants reaching towards 300. Some of these companies have paid 5 per cent. dividend for a number of years.

The largest English-built dredges have close-connected buckets of 12 cu. ft. capacity, a large proportion 8 and 9 cu. ft. The open-connected dredges range from 6 to 15 cu. ft. buckets.

Dredging depth ranges from 30 to 80 ft., and dredges are being built to dig 100 ft.

Output varies according to bucket capacity and the rate at which the ground can be efficiently treated. The open-connected bucket is run from 14 per minute for the smaller to 12 per minute in the larger sizes. The close-connected bucket from 28 to 18 per minute.

Maximum output is calculated:

$B \times S \times 60 \div 27 =$ cu. yds. max. per hour. $S =$ number of buckets delivering per minute.
$B =$ capacity of buckets in cu. ft. $27 =$ number of feet per cubic yard.

Roughly, 1 cu. yd. is calculated 1½ tons.

To obtain the estimated output, one-third is deducted from the maximum, but this is not always reached; buried timber and large boulders tend to decrease output. The removal of barren overburden (to reach pay dirt) and difficulties of cleaning up bedrock lessen the profitable dredging time. A further factor is time lost in cleaning up the tables or launders to recover the gold or tin. Working time varies; many dredges have averaged over 600 hours per month.

Working costs vary with difficulties of ground, cost of fuel, and labour.

Comprised in above are European and native labour, fuel, stores, spares, camp upkeep, passage money and leave pay, management expenses, depreciation of plant, insurance.

The aggregate cost of running a small dredge does not vary greatly from running a larger one, and ground that is too low in value to give a return on a small dredge could be made to pay with a dredge of large output. With favourable conditions, dredges on easy ground have been run for as low as 1·5*d.* per cu. yd. treated. Large tin dredges in Malay 3·13*d.* to 4·0*d.* per cu. yd. treated.

TIN DREDGES.

NEW ZEALAND TYPE DREDGERS (GOLD).

Size of Buckets.	Estimated Capacity. In cu. yds.	Digging Depth below Water-Line	Weight including Hull.	Price, f.o.b. London.	Horse Power.
Cu. Ft.		Ft.	Tons.	£	
3	30,000	20	100	5,000	35
4	40,000	20	180	9,000	—
5	50,000	26	220	13,000	56
6	60,000	40	280	16,000	—
7	74,000	32	350	20,000	180

The Californian or American dredge is costly, very heavily built, with close-connected buckets, digs with spuds, and till lately built with wooden hulls.

For properties where the transport is high, as in parts of Siberia, and where heavy repairs are difficult, a well-built New Zealand type of dredge, with ample stock of spares, is preferable. Indeed, its choice is imperative in some cases, for the high transport costs to some properties exclude the use of the ponderous American type of dredge. On the other hand, cheap transport, access to machine shops, and with heavy or stiff semi-cemented gravel, or large deep deposit of fair digging gravel (the latter permitting the handling of enormous daily yardages) are conditions favourable to the use of the American dredge.

SECTION XXXIX

PART II

MINERAL VALUATION.

(By Professor Henry Louis, M.A., D.Sc., A.R.S.M., M.Inst.C.E., etc.)

General Principles.

Under the head of Mineral Valuation are included two somewhat different valuations, namely, that of a mineral property, whether worked or not, and that of a mine as a going concern ; the difference arises from the fact that the proprietor of the minerals does not as a rule work them himself, but disposes of them, usually for a royalty, to the mine-owner who works them. In cases where the mine-owner is also the proprietor of the minerals, it is generally more convenient to value the mine, the royalty derivable from the ownership of the minerals being included as a part of the profit derivable from the mining operations.

In either case it is necessary to determine the present value of a number of annuities, the latter being the annual revenue derived from the royalties or the profits, as the case may be.

The amount of the royalty per ton is generally known or can be closely approximated, being the price paid or to be paid for the mineral in its unsevered condition as it lies in the deposit.

The profit per ton must be estimated from the probable cost of working and the probable value of the mineral in its marketable condition.

The tonnage to be wrought annually must be estimated, having due regard to all the conditions of the deposit, and should be taken to be the amount that can be extracted, so as to produce the maximum total profit over the period under consideration. It is obvious that a deposit worked out with excessive rapidity will yield no profit when the interest on the capital outlay required to so work it exceeds the profit derivable from working ; on the other hand, if worked excessively slowly, the standing charges may exceed such profit. Between these extremes lies the rate of economic working ; it will generally be found that there is a considerable range of working rate, within which the economic results are practically uniform, and the best rate within that range is usually determined by market conditions or other purely commercial considerations.

The probable total quantity of mineral that can be economically produced from the property must next be calculated, meaning thereby the amount which is as likely to be exceeded as to be fallen short of ; it is obvious that the quantity that can actually be produced from any property can never be known until the property has been exhausted, when the information is naturally valueless. Hence the question becomes one of probabilities, never one of actually ascertained figures, and must always be considered as subject to the laws of probability in the mathematical sense. The quantity thus estimated divided by the estimated or proposed annual output determines the probable life of the property ; if the latter is held under mineral lease, the period of which is less than the probable life, the length of the lease is substituted for the probable life in the calculations.

Sometimes not only the tonnage but also the assay value of the mineral deposit enters into the calculation, and in either case it is never a certainly known figure, but always the most probable figure, that has to be employed. Thus, where the value of a mineral deposit depends upon its thickness and its assay value, let the ascertained most probable thickness be T units and the ascertained most probable value be V units ; as neither are known with certainty, these figures should be written $T \pm t$ and $V \pm v$ respectively, where t and v are the respective probable errors ; then since the probable error of the product VT is $\sqrt{T^2v^2 + V^2t^2}$, the value of the deposit will be a function of $VT \pm \sqrt{T^2v^2 + V^2t^2}$. (See *Mineral Valuation*, by H. Louis, p. 128.)

In the following formulas, the annual income = annual tonnage × royalty per ton, or annual tonnage × profit per ton, as the case may be, will be designated by a.

The number of years of life of the property or of the lease will be designated by n.

The problem then becomes that of determining in the first instance the present value (P) of a series of annuities of £a for a term of n years.

Generally the ordinary compound interest formulas apply, which show that X pounds invested at a rate of interest i per unit will amount in n years to $X(1+i)^n$, and conversely the present value of Y pounds payable at the end of n years, allowing interest at rate i, is

$$\frac{Y}{(1+i)^n}.$$

(See page 3, Section I.)

The main difficulty in all mineral valuations lies in determining the proper rate of interest to allow. The rate of interest in operations in which there is practically no risk, that is to say where the probability of the payment of capital and interest in full is practically unity, may be taken to be the rate obtainable by investment in such securities as Trustee Stocks. In all mining operations the risk is always greater, or in other words the probability of payment is less, hence a higher rate of interest is demanded to cover the risk. If i be the safe rate of interest the risk rate may be expressed by ri, where r is a number greater than unity, depending upon the conditions of the case, and which may conveniently be described as the risk factor; it may also be defined as the reciprocal of the fraction representing the probability of success, and is therefore greater the more hazardous the nature of the enterprise. In practice the risk factor ranges from 2 to 5, being lowest in well-proved bedded deposits, the uniformity of which has been determined by experience, and highest in veins or masses in which values are known to be very irregularly distributed. **It is less where money is invested merely in the purchase of a mineral property than when it is invested in a mining enterprise, because royalties form a first charge on revenue and are almost invariably secured on the assets of the mining enterprise, whereas the latter can take only remainder profits, which are totally unsecured.**

The determination of a proper risk factor is the principal problem that the mining engineer has to solve in valuations.

Present Value.

Let $ri=s$, so that s is the rate of interest *per unit* that is required in any given case.

Some writers call i the 'accumulative' and s the 'remunerative' rate of interest; the term 'risk rate' will be adhered to here in order to emphasise that the high rate is required in compensation for the risk that the investor runs. Of course i is governed by the money market, and is the rate of interest paid on investments in Government stocks and similar first-class securities; it will be noted that s varies directly with i.

The value of the mineral property or mine *at the moment of commencing profitable operations* is therefore P, the present value of n annuities of £a. This should obviously be equal to the present value of sums of £a payable at the end of each of the first, second, third, etc., years up to the end of the nth year, and this sum

$$=\frac{a}{s}\left(1-\frac{1}{(1+s)^n}\right).$$

It is sometimes useful to remember that, if A is the present value of £a due at the end of n years,

$$P=\frac{a-A}{s}.$$

The expression for present value given above is often spoken of as Inwood's formula. Calculations are easily made by this formula; the table on page 6, which gives the present value of an annuity payable at the end of each year for a varying number of years and at various rates of interest, obviates this calculation, as it is only necessary to multiply the present value taken from the table by the amount of the annuity. The table gives the values of

$$\frac{(1+s)^n-1}{s(1+s)^n}$$

for different values of n and s; in the headings of the table the rates of interest are given per cent. and not per unit. Again, the sum of n annuities of £a payable at the end of each year up to the end of the nth year is

$$\frac{a}{s}\left((1+s)^n-1\right),$$

and the present value of this sum is

$$\frac{a}{s}\cdot\frac{(1+s)^n-1}{(1+s)^n}$$

as before. Again, the annuity may be looked upon as part interest on the present value, the remainder being applied annually to the reduction of the capital, interest being paid each year on the unredeemed portion of the capital. If calculated on this basis the same result is obtained.

There is yet another method of looking at the problem. The annuity exceeds the simple interest on the present value by an amount equal to $a-Ps$ in each year; if this difference be allowed to accumulate at rate s for n years it will amount to

$$\frac{a}{s}\cdot\frac{(1+s)^n-1}{(1+s)^n}=P,$$

hat is to say, to the original capital, as it obviously should do, because the purchaser of n annuity, spending each year only the interest on the capital invested, should get back his apital at the end of the period, because this operation would be equivalent to investing the apital at the given rate of interest during the given term of years.

This last method of looking at annuities has given rise to another method of calculating hem, known from its originator as Hoskold's method. He considers that the risk rate of nterest s should be allowed upon the capital, but that the difference between the annuity and he interest $(a-Ps)$ should be looked upon as accumulating at a safe rate i because it is not ecessarily invested in the risky mining operation. This view gives rise to the formula

$$P = \frac{a}{\frac{i}{(1+i)^n-1}+s}.$$

This value may be taken out from any ordinary tables as follows :—

$$\frac{(1+i)^n-1}{i}$$

s the amount of £1 at interest i for n years, and the reciprocal

$$\frac{i}{(1+i)^n-1}$$

s the sinking fund for the repayment of £1, *i.e.* the sum to be set aside annually and allowed to ccumulate at interest i in order to amount to £1 in n years. These values are obtained from ables (see pp. 3 and 9). The denominator of the fraction in Hoskold's formula can be taken nt by adding the risk rate to the sinking fund for £1 at interest i for n years.

This method is often used, but is not one that fairly answers all the tests of a true annuity ormula. Nevertheless, it is used by valuers on the grounds that the difference between the nnuity and the simple interest cannot, in fact, be invested at the risk rate s, but must be invested it the safe rate i, and that this method, therefore, more correctly represents what would obtain n actual practice.

Hoskold's method depends upon considering only one out of the various methods in which he true annuity formula may be looked at; obviously the two can be made to give the same esult by selecting suitable risk factors in each case. Thus if r is the risk factor in Inwood's ormula, and r' in Hoskold's method, the present values will be the same whichever formula be ised, when

$$r' = \frac{r(1+ri)^n}{(1+ri)^n-1} - \frac{1}{(1+i)^n-1}.$$

It follows that r' must be greater than r; in other words Hoskold's method allows a rate of nterest higher than the stipulated risk rate, and hence puts a lower present value on a given nnuity. It need hardly be said that both his method and the ordinary method provide equally or the replacement of the original capital, if suitable sums are set aside in each case out of the nnuities received.

Hoskold's is the generally accepted method of dealing with mineral valuation; it is, however, bvious that year by year a portion of the original purchase price (or present value) is withdrawn rom the speculative investment and set aside to form the sinking fund for its repayment, whilst he risk rate of interest is still being paid upon the whole of the original purchase price. It night, however, fairly be stipulated that this risk rate is only to be paid upon such portion of the riginal capital as has not yet been redeemed by the sinking fund, which accumulates as before it the rate i per unit, whilst the portion of the capital thus withdrawn from the risky investment, hough not yet really returned to the inventor is credited with interest at the rate j per unit of course i and j may in some cases be the same). On the basis of these stipulations, the following ormula results :—

$$P = a\,\frac{(1+s-j)^n-(1+i)^n}{s-(j+i)+s\,[(1+s-j)^n-(1+i)^n]}$$

(*H. Louis*, '*Trans. Inst. Min. Eng*,' lxx., 1925, p. 368.)

Since an investor in mines usually stipulates that he shall receive the risk rate of interest on his investment throughout the whole life of the mine, the Hoskold formula, though possibly less equitable, is generally applicable.

Increasing and Decreasing Values

The above methods of valuing mineral properties tacitly assume that the mine will forthwith commence to produce at its full rate of output and will continue to do so until the mineral is worked out; this is, of course, not the case in practice, a mine only reaching its full output after several years, and this gradually declining again as the deposit approaches exhaustion. There would be no difficulty in allowing for this in the valuation, but as a rule it is neglected; as has already been pointed out, the figures on which the valuation is based are only probable, not actual figures, so that there is no use in endeavouring to attain minute accuracy in these computations.

There is obviously no difficulty in introducing these refinements if it is considered desirable; the computation is made as above for the estimated period of full production deferred during the period of production at a lower rate than the full output; the income expected in each year of output less than full output is calculated and its present value is determined, and all these present values are added together to obtain the total present value of the property.

The author has recently pointed out that this formula demands a risk rate also on the portion of the capital no longer at risk, and suggests the following :—

$$P = a\,\frac{(1+s-i)^n-(1+i)^n}{s-2i+s[(1+s-i)^n-(1+i)^n]}$$

(See *Trans. Inst. M.E.*)

If preferred, calculations can also be made directly, whether the annuity increase or decrease in arithmetical or in geometrical ratio. Let c be the income in the first year and let it increase or decrease by b each year, so that the income for the second year is $c \pm b$, for the third year $c \pm 2b$, etc., during n years. Then the present value of this annuity on the Inwood method is :—

$$c\left(\frac{(1+s)^n-1}{(1+s)^n s}\right) \pm \frac{b}{s}\left(\frac{(1+s)^{n-1}-1}{(1+s)^{n-1}s}\right) \mp \left(\frac{(n-1)b}{s}\cdot\frac{1}{(1+s)^n}\right).$$

These values can be taken out from the tables: the first expression is, as before, the present value of £c for n years at rate s; the second is the present value of £$\frac{b}{s}$ for $(n-1)$ years at rate s and the third is the principal which will amount to £$\frac{(n-1)b}{s}$ in n years at rate s. (See Present Value Table, p. 11.)

If Hoskold's method be used, the present value is :—

$$\frac{c+\frac{b}{i}}{\frac{i}{(1+i)^n-1}+s} \mp \frac{nb}{i-s+s(1+i)^n}$$

The first part of this expression is the present value of an annuity of £$\left(c+\frac{b}{i}\right)$ calculated for n years by Hoskold's method; in the second expression $s(1+i)^n$ is the amount of £s at interest i for n years (see table, p. 3).

Again, let c be the income for the first year and let it increase geometrically by a ratio k, so that the income for the second year is ck, for the third ck^2 . . . etc., during n years. Then the present value of the annuity on Inwood's method is

$$\frac{c}{(1+i)^n}\cdot\frac{k^n-(1+i)}{k-(1+i)}, \text{ or, if } \frac{k}{1+i}=f, \text{ it is } \frac{c}{1+i}\cdot\frac{f^n-1}{f-1}.$$

On Hoskold's method the present value becomes :

$$c\cdot\frac{(1+i)^n-k}{1+i-k}\cdot\frac{i}{i+s[(1+i)^n-1]}.$$

All the above calculations are based upon the hypothesis that the annuity is paid at the end of each year; in practice royalties are mostly paid quarterly, and mining dividends at least half-yearly. To meet this point, for n substitute $2n$, and for s substitute $\frac{s}{2}$ when payments are made half-yearly, these becoming $4n$ and $\frac{s}{4}$ respectively when payments are made quarterly.

Dead-rent.

In computing the present value of mineral royalties 'certain rent' or 'dead-rent' has sometimes to be taken into account. Mineral leases usually stipulate for a definite dead-rent, which may be in addition to the variable royalty, or may be a merging dead-rent, that is to say that the amount of royalty to be paid is determined by the tonnage which is in excess of that which corresponds to the dead-rent at the agreed royalty rate. As the dead-rent is payable in full, whatever the results of the mining operations, its present value must be calculated not on the mining risk rate of interest, but on a rate obtained by multiplying the standard safe rate by a factor depending only on the financial stability of the lessee. This consideration may be neglected when the dead-rent is very small compared with the expected annual royalty, but must be taken into account when it is considerable, the present value of the whole royalty, in the case of an additive dead-rent, or of the excess of royalty, in the case of a merging dead-rent, being computed as above and added to the present value of the dead-rent.

Relinquishment.

When, as is often the case, the lessee has power to relinquish the lease after a given number of years or at stated intervals, there is a risk that the lease may be cancelled because the mine proves unprofitable or because the deposit is exhausted, and the rate of interest applicable to the dead-rent during the definitely fixed period is estimated as above, but it must be multiplied by a risk factor representing the probability of such relinquishment in computing the present value of the dead-rent during the successive periods. Here, again, the difficulty of the problem consists entirely in determining the proper probability factor.

Deferment.

In opening a mine there is always a period of development during which no mineral is produced, or at any rate none is produced profitably, whilst the main capital expenditure in the way of shafts, adits, plant, machinery, etc., is incurred. The present value at the commencement of the profit-producing period as found above must therefore be looked upon as deferred for the requisite number of years and the actual value determined. If V be the actual value at the commencement of mining operations and d the number of years occupied in development,

$$V = \frac{P}{(1+s)^d}.$$

The risk rate of interest must be taken, because the capital is being spent and is subject to the full risks of the mining operation.

The annuity formula and deferred value formula may be combined, thus :—

$$V = \frac{a}{s} \cdot \frac{(1+s)^n - 1}{(1+s)^{(n+d)}}.$$

It is, however, better as a rule to make the computation in the two stages, as above.

The table on page 11 facilitates calculation of actual values; it gives the present value of £1 due at the end of a varying number of years at varying rates of interest; the present value taken from the table and multiplied by P gives the value of V. This table gives the values of

$$\frac{1}{(1+s)^d}$$

for different values of d and s, rates of interest being expressed in the headings as percentage rates.

Mr. O'Donahue has proposed a method of calculating deferments that has some analogy with Hoskold's method of computing the present values of annuities, being also a two-rate method. He considers that simple interest at the risk rate s should be allowed on the actual value V, whilst the interest assumed to fall due accumulates at the safe rate i, whence

$$V = \frac{P}{1 + \frac{s}{i}\left[(1+i)^d - 1\right]}.$$

Since interest is never in fact paid nor payable on the actual value, this method cannot be recommended. This formula and the ordinary deferment formula may be connected as follows :— Let r be the risk factor in the ordinary method and rf the risk factor when O'Donahue's method of deferment is employed; then

$$rf = \frac{(1+ir)^d - 1}{(1+i)^d - 1} \text{ and } r = \frac{\sqrt[d]{1 + r'[(1+i)^d - 1]} - 1}{i}.$$

In some cases, however, where two different rates are involved, another method must be adopted. In the most general case, it is required to determine the present value, V, of a mine that will take d years to develop, during which time no profits are earned, and which will then yield a profit of £a per annum during n years, it being a condition that the original capital shall bear interest at the risk rate s, but that all accumulations can only be invested at the ordinary investment rate i. At the end of the n years the investor is entitled to receive back his capital plus the accumulations of interest (Vs per annum) at the rate i or

$$V + Vs\,\frac{(1+i)^{n+d} - 1}{i}.$$

This must be equal to the amount of an annuity of a per annum for n years, or

$$\frac{a}{i}\left[(1+i)^n - 1\right].$$

Equating :—

$$V = \frac{a\left[(1+i)^n - 1\right]}{i + s\left[(1+i)^{n+} \quad -1\right]}$$

This is the same result as follows from the method of calculating deferred annuities, published by Mr. George King in his 'Theory of Finance.' Further, if $d = 0$, the above formula becomes the ordinary Hoskold formula given above.

Capital Expenditure.

From the present value, V, as determined by any of the above methods, the capital necessary to bring the mine into full work must be deducted in order to obtain the value of the mineral property; if the capital expenditure is spread over several years, the present value of this deferred expenditure must be computed at the ordinary investment rate i, and the sum thus found deducted from V.

Deferred Development.

It occasionally happens that the valuation is required of a mineral property which it is not intended to commence to develop for a number of years; in this case the present value must be calculated as the present value of a sum V, the payment of which is deferred for the given period at a rate of interest i per unit. The risk rate of interest must not be taken into account because there is no mining and therefore no mining risk. If the value of V has been properly determined, making all due allowance for mining risks, the problem resolves itself into determining what capital sum must be invested in safe securities in order to produce the sum V at the time when mining operations are to be commenced. Special attention is drawn to this point, because mistakes are often made in confusing the rate of interest required during the development period and the rate required during the period preceding development, the latter depending on ordinary acutarial considerations and not on the risks incidental to mining.

Investment Value.

Finally, in comparing investments in mines or in mineral properties with other investments of capital, the effect of Income Tax as well as of Mineral Rights and Increment Value Duties must be taken into account. Mines and minerals both constitute wasting assets, but income tax is charged upon the gross revenue derived therefrom, hence not only on the true revenue, but also on that portion of the gross revenue that ought to be looked upon as forming a sinking fund set aside to replace the original capital at the end of operations; mineral rights duties specifically affect only mineral properties and thus constitute an additional charge upon these. In both these respects, therefore, these investments are at a disadvantage compared with ordinary investments, a fact that requires due consideration in computing mineral valuations as a basis for the investment of capital.

FURNACES.

CLASSIFICATION OF FURNACES.

Furnaces in which the Charge and the Fuel are Intermingled.

1. Hearth Furnaces.

(*a*) With blast. Forge for smithing. Grate for zinc-white manufacture.

(*b*) Without blast. Heap and stall for coking and roasting. Trough for liquation and crossing.

2. Shaft Furnaces.

(*a*) With forced draught. Blast furnaces for smelting ores of iron, copper, lead, etc. (see p. 2752). Cupolas for iron-foundry practice (see p. 2655).

(*b*) With induced draught. Only rarely employed.

(*c*) With natural draught. Furnaces for smelting readily fusible ores. Kilns for calcining, roasting, etc.

Furnaces in which the Charge and the Fuel are Separate.

1. Reverberatory Furnaces (Radiation).

(*a*) With forced draught. Furnaces for the refining of metals and the smelting of ores.

(*b*) With natural draught. Furnaces for the roasting of ores. Furnaces for the manufacture of wrought iron, etc.

2. Crucible, Retort, Muffle, etc., Furnaces (Conduction).

(*a*) With solid, liquid or gaseous fuel (see p. 2658)

(*b*) With electricity (see p. 2661).

Furnaces in which the Charge Supplies its own Fuel.

(*a*) Preheated furnaces with solid charge. Kilns for ore-roasting. Beehive coke ovens.

(*b*) Preheated furnaces with liquid charge. Converters for refining, etc.

(*c*) Non-preheated furnaces with solid fuel. Blast-roasting furnaces with up and down draught.

Electric Furnaces Heated by Resistance Effects

(*a*) The charge is included in the electric circuit. Héroult aluminium furnace. Kjellin induction furnace (see p. 2661).

(*b*) The charge is heated by means of an electrically-heated conductor (see p. 2661).

Electric Furnaces Heated by Arc Effects.

(*a*) Direct heating. The charge forms one or both poles of an electric arc (see p. 2661).

(*b*) Indirect heating. The charge is enclosed in a space heated by an electric arc (see p. 2661).

Electric Furnaces Heated by Combined Resistance and Arc Effects.

Girod, Greaves-Etchells, Héroult, etc., steel furnaces (see p. 2661).

SHAFT FURNACES.

BLAST FURNACES.

(*Contributed by Colin Livingston.*)

A blast furnace should be designed to suit the materials used in smelting; successful designs can best be accomplished by keeping in view the best practice with particular materials. No general formula for the design of all blast furnaces, for a given output, is possible. The following points are common to all successful blast furnace plants, and should be kept in view, in new construction:—

The aim of all blast-furnace work is the production of a good marketable iron at the lowest cost. Low costs rest chiefly on low fuel consumption; low fuel consumption is governed by the quantity of fuel, dryness and temperature of blast, with correct furnace lines for the ores smelted.

Blast temperature is entirely one of stove capacity; it is essential that stove capacity should be on the generous side.

Output will depend on capacity of furnace, diameter of hearth, and will vary according to materials used, quantity and pressure of blast, dry or wet blast, temperature of blast; blast pressure should be able easily to penetrate to centre of furnace.

Bosh line angles are found to vary very little; short steep bosh lines are a decided advantage with most materials. Leading American blast-furnacemen attribute some of their remarkable results, in part, to low steep boshes and large hearths.

Furnaces with hearths 20′ 9″ in diameter are in successful operation.

In general practice, furnace shafts should have a batter of at least 0·625 in. in 12 ins.; where fine ores are smelted this could be considerably increased with advantage. Diameter of bell should be 4 ft. to 4 ft. 6 ins. smaller than diameter of throat.

The furnace should be entirely enclosed in a strong steel shell, from the hearth level up.

All parts of furnace top work should be securely fixed to main shell structure.

In designing blast-furnace details the main considerations should be (1) efficiency, (2) strength, (3) simplicity.

The number of gas offtakes should be such that the gas leaves furnace as slowly as possible, so as to avoid carrying dust over to flues.

The height of furnace varies from 80 to 100 feet; with the materials used, each district has come to fix the height found most suitable for its particular conditions.

Sufficient relief area, by bleeders or explosion doors, should be provided on top of furnace to prevent injury from slips; the relief should, if possible, be directly upwards.

For hearth well and boshing nothing but the best quality of fire-brick should be used. The ricks should not be too large, so that they may be thoroughly burned.

For the upper lining a fire-brick with more wear resisting qualities can be used.

Care should be taken that all bricks when laid are properly bedded and tight built, with fire-ay joints as thin as possible.

In relining a furnace, the bear in old hearth need not be removed, but simply levelled to start uilding well on.

This will save much hard work and expense—experience will prove that nothing better for hearth can be put in.

Some means should be taken to preserve the upper lines of furnace from wear where stock om bell strikes brickwork; a satisfactory way of doing this is to insert with brickwork alternate ayers of cast iron or steel plates. In normal working, the stock level should be kept just high nough to allow bell to swing freely when full open.

The number of tuyeres is not so important (if sufficient area for output is provided) as equal istribution and penetrative power of blast.

There should always be a reserve of blowing power available after providing for normal naximum requirements.

Where blast-furnace gas is fully utilised and gas economy a necessity, the blowing should e done by gas engines. Where there is a surplus of gas the turbo-blower can be installed with dvantage, and will prove an ideal blowing engine. Reciprocating steam-blowing engines are ill being installed, but only in cases where conditions make it unsuitable or inconvenient to iscard existing plant.

Cooling.—Apart from tuyeres, jumbos, and hearthcooling, any cooling appliances provided or the bosh or upper lining should be carefully considered; external or spray-cooling has the reat advantage that leakage of water into the furnace is prevented, or rather more easily de-ected. The trouble caused by water leakage from blocks inserted in the building is considerable, nd can never be fully known; it is often when the damage is done the leak is located. The atest practice is to spray-cool the bosh and sometimes the entire outside shell; by this means much thinner brickwork can be used, the furnace preserves its original lines longer, and the ning has a longer life.

Stoves.—Should be as simple in design and equipment as possible, with ample facilities for leaning and inspection, and have a good chimney draught.

Using unwashed gas, chequers should not have less than 9-in. by 9-in. openings; with washed as smaller chequer openings can be used, giving greatly increased heating surface for same size of hell, and higher blast temperatures and lower chimney temperatures for same gas consumption. Openings 3½ ins. × 3½ ins. with 2-in. thick walls have proved satisfactory in practice.

In latest practice for heating stoves the gas and air is forced by special fan into combustion hamber, the stove burns more gas, which gives higher and more regular temperatures, with a aving up to 25 per cent. in stove construction for a given production.

Preheating the blast before entering the stove proper is in successful operation with increased verage temperatures.

It is decided economy to clean blast-furnace gas, as better results are obtained.

It is no advantage to go beyond 1,550° F. in stove heats, any fuel economy being more than ff-set by stove repairs.

Better results with certain ores will sometimes be obtained by running on lower blast heats; his may seem to conflict with theory, but in blast-furnace work it is often the case that sound heory follows successful practice.

Uniform ore mixtures and quality of fuel and flux should be kept in view, rather than frequent hanges of ore mixture, with varying qualities of fuel and flux. It is an advantage to break hard lense ores, especially magnetites.

The approximate saving in lbs. of coke per ton of iron by increase in blast temperature is s follows:—

1,000° to 1,100° F.,	50 lbs.
1,100° „ 1,200° „	40 „
1,200° „ 1,300° „	30 „
1,300° „ 1,400° „	20 „

Dry Blast.—Average results with dry blast give a saving of 10 per cent. in fuel consumption vith 10 per cent. increase in output, more regular grade of metal, and more regular working onditions.

A blast furnace in its working and results responds readily to improper treatment; proper egulation of flux has much to do with this, and the formation of a correct slag is all important.

The slag should not be too basic or limey ; this causes the furnace to become stocky and go up. If the slag is too acid the furnace will drive harder, but trouble is sure to result with grad and quality of pig.

When the lime content of slag is high it will prove profitable to make such slag into cement the slag form from furnaces making Bessemer iron will generally be found suitable for this purpos Most blast-furnace slags can be easily made into first-class building bricks.

The slightest indication of irregular furnace working should be promptly attended to an put right ; irregular conditions will probably show first in change of slag or irregular settlin of stock. The appearance and degree of fluidity of the slag is the furnaceman's best indicatio of working conditions.

Irregular working at tuyeres is generally caused by water leakage from jumbos and tuyer blocks. It is quite possible for tuyeres to be shut by water leakage, in spite of very carefu watching.

No tuyere in a regular working furnace will close while the blast is on except by water leakage.

Irregular working at tuyeres is sometimes caused by an alteration in burden ; in this cas every tuyere will give trouble, which will continue till the trouble has been put right.

The best way to open tuyeres that may have been hard closed by slips, irregular working or water leakage, is by the application of oxygen ; the apparatus used is simple and cheap : th worst stuck tuyere can be opened in a few minutes.

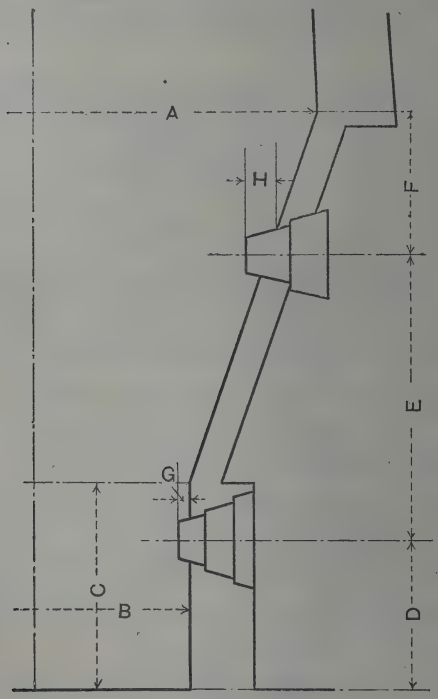

FIG. 1.—Bosh Tuyere.

Bosh tuyeres, it is claimed, increase the output of a furnace 20 per cent. with a slight increase in fuel consumption and more regular working. Fig. 1 and the 'Table of Bosh Tuyeres' give sizes and position of bosh tuyeres from actual practice.

FLUE DUST.

The treatment of flue dust has developed into a distinct branch of blast furnace work ; he true solution of the problem is to keep the dust in the furnace, thereby increasing roduction and reducing costs. Flue dust is caused chiefly by (1) fine ores ; (2) soft fuel ; 3) hard driving ; briquetting or sintering gets over the first, but furnace design will need to e adapted to surmount the second and third.

For a comprehensive schedule of blast-furnace data see ENGINEER'S YEAR-BOOK, 1927, p. 2580–2591.

CUPOLAS.

BLAST-QUANTITY AND PRESSURE IN CUPOLA WORKING.

An average of 120—in terms of quantity of air in pounds, multiplied by $\sqrt{}$ pressure in ounces— required to melt one ton of ordinary phosphoric iron.

The maximum output of metal melted per hour is more nearly comparative to diameters of upolas than areas of same.

The maximum output of a cupola will be obtained when the pressure and quantity of the last in ounces and pounds per minute respectively are so adjusted that $\frac{W \sqrt{P}}{D} = 330$, D being he diameter of the melting zone in feet. Any further increase in the product $W \sqrt{P}$ results in xcessive oxidation of the metal in the cupola.

Iron melted in a cupola is affected in hardness directly as the pressure of blast used, so that he total area of the tuyeres employed should be regulated according to the class of iron being nelted, small areas being used when greater hardness is required.

The height of the cupola from the top tuyeres to the charging-door sill should *not be less* than wo and a half to three times the diameter across the melting zone.

The coke consumption in a well-designed cupola need not be more than 0·075 lb. to 0·09 lb. per pound of ordinary phosphoric iron melted, when the coke contains from 90 to 92 per cent. of carbon. (*F. J. Cook.*)

CENTRIFUGAL FANS FOR CUPOLAS AND SMITH'S FIRES.

To give the high pressure required to supply air to Cupolas and Smith's Fires the fans must be of the 'centrifugal' type and suitably designed. They usually have smaller inlets and outlets than those used for ventilating, as pressure, not volume, is the essential feature.

Care is required in the choice of a suitable fan, as the efficiency varies within wide limits with the design.

CENTRIFUGAL FANS FOR CUPOLAS, SMITH'S FIRES, ETC.

9	60	10	1,600	35	60	1,250	24
10	66	13	1,450	42	80	1,080	32

The duct to the cupola or fires should be made at least as large as the fan outlet; in lon lengths it should be made larger, so as to reduce friction, which increases the power to no purpos If the ducts are below ground cast iron is the best material; sheet-steel ducts ⅛ in. thick, wit flanged joints, are also very suitable, especially if carried above ground. If earthenware pip are used great care must be taken to lay them straight, with good, sound, and permanent joints.

(*Sturtevant.*)

Forge Air Pressure.

The air pressure for a forge commonly varies from 2 to 4 ozs. per square inch, with an averag of about 3 ozs. A pressure of 4 ozs. at the blower has been recommended when the averag number of fires does not exceed ten, and a pressure of 5 ozs. when the number is more than twelve Small forges with the blower close to them are adequately supplied with 1½ ozs. pressure. I the blower is some distance away and a long discharge pipe with many bends leads to the forge even though the latter be small, it may be necessary to carry 3 ozs. pressure or more, to overcom the friction in the air ducts. The volume of free air required by the average forge fire is abou 140 cubic feet per minute. The exhaust fan for a blacksmith shop should have a capacity approxi mately four times that of the forge blower, and should operate under a pressure of about ¾ oz.

REVERBERATORY FURNACES.

In a reverberatory furnace the material to be heated is contained in a long horizontal o slightly sloping hearth, the heat being supplied by flames and hot gases which travel over it. A considerable amount of heat is radiated on to the hearth from the arched roof of the furnace The proportions of the various parts of the furnace are important, as if the roof is too high the gases will not 'lick' the hearth, but will travel close to the roof. Care must be taken to have a sufficient volume of gases in the furnace, as otherwise the upper part of the hearth will be too cool There is a strong tendency to open the exit damper too wide. When in constant use, a reverbera tory furnace heated by producer gas is more economical than one heated by solid fuel.

KILNS.

A kiln is a furnace which is filled almost completely with the articles to be heated. Usually the flames and hot gases from the fuel circulate among the goods and raise them to the required temperature by conduction. When contact with the kiln gases would spoil the goods, they may be enclosed in fireclay cases or a *muffle furnace* may be used.

MUFFLE FURNACES.

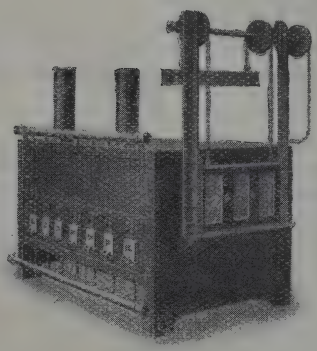

Fig. 4.

A muffle furnace is one in which the articles or materials to be heated are protected from direct contact with flames and hot gases from the fuel, but the term is sometimes used loosely for any kind of furnace heated by town's gas instead of solid fuel. The latter kind of furnace is extensively used for annealing, normalising, case-hardening, tempering, forging, and other heat treatments of iron, steel, and the non-ferrous metals.

Fig. 4 shows an oven furnace heated by the 'Lopress' system, in which gas at ordinary main pressure is used in conjunction with air at approximately 4-in to 6-in. water gauge. No compressor is necessary, the requisite air supply at this pressure being derived from a fan. Very rapid heating and much higher temperatures can be obtained compared with natural-draught heated furnaces. The 'greasy' flame so essential to annealing work on a large scale can be produced to perfection, while economy is ensured by regeneration of the air supply to the burners.

The following are figures from actual practice :—

Operation.	Load.	Duration.	Cub. ft. ton.
Annealing H.S. steel	3½ tons	8 hrs.	3,000
,, steel	3½ tons	15½ hrs.	6,000
,, C.I. parts packed in filings in boxes	2,000 lbs.	3 hrs.	3,360

High-speed Tool Steel.*

In no heat treatment of metal is uniformity of furnace mperature more important than in the treatment of igh-speed steel. Tool makers nearly always state the ract temperature required for various processes.

The furnace shown in fig. 5 enables any temperature be quickly reached and regularly maintained down to ie very narrow limits frequently required by particular eels. Whatever the composition of the steel. this rnace enables the operator to produce good tools, ving the maximum of service, and avoiding the waste expensive material and time due to under, over, or regular heating, etc.

The upper chamber is heated by waste heat from the wer, and serves to preheat the tools, etc., before they re put into the lower chamber, thus raising them to a edium temperature preparatory to the final rapid eating necessary to bring them to the hardening mperature

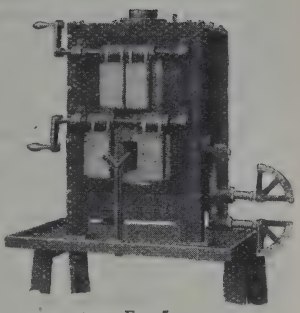

FIG. 5.

CRUCIBLE MELTING FURNACES.

(L. C. Harvey.)

'Lift-out Crucible' or Pit Type Furnaces.—These are supplied where requirements of molten metal are small, or in cases where it is preferable to melt in relatively small apacity crucibles. *Natural Draught Coke Furnaces* can be either connected up to one main flue nd chimney or can be provided with smaller collecting flues, each flue having a chimney to erve a small number of fires, or again, each fire can have its own small stack.

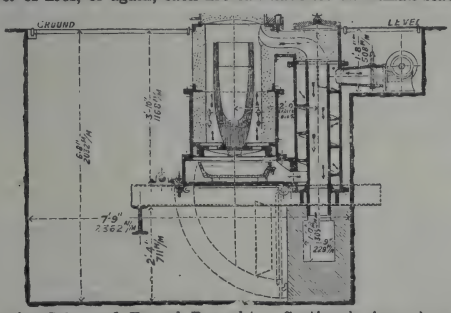

FIG. 6.—Furnace for Coke and Forced Draught. Sectional view, showing ground level.

Forced Draught Coke Furnaces (fig. 6) can be similarly arranged as regards provision for hausting the waste gases, and as they are not dependent upon chimney pull the heights of acks are considerably less than those required for natural draught furnaces.

It is usual to supply air from a blower or fan of sufficient capacity to feed any number to the whole of the plant. Forced draught offers the advantages of (*a*) independence of mospheric conditions, and, therefore, absence of variation in chimney pull; (*b*) quicker ating qualities of furnaces; (*c*) a greater degree of heat intensity than is possible under all nditions in natural draught furnaces.

Oil-fired Furnaces.—These can be fitted with burners to work with compressed r at 20-30 lbs. per square inch, depending to a large extent upon the temperature desired, ie higher pressure effecting a more perfect atomisation of heavy grades of fuel, or with low ressure burners which run with a pressure of only $\frac{3}{4}$ lb. per square inch for all temperatures to that necessary for melting mild steel and nickel.

The former require an air compressor, which is a relatively expensive machine, and may velop 5 to 10 h.p. per burner, whereas the latter needs only the ordinary open high-speed n, and the burners will take $1\frac{1}{2}$ to $2\frac{1}{2}$ h.p. according to size of the furnace, etc. Almost any ade of commercial fuel oil can be used with either type of burner, and this is fed to the rners by gravity.

* See also p. 1136

Producer Gas can be applied to lift-out crucible furnaces if these are made in the multip form, viz. several crucibles in one common melting chamber, or several crucibles in separa chambers, but exhausting into one air or gas heating regenerator.

For ordinary low-power producer gas, 135 to 175 B. Th.U. per cubic foot, is essential to prehe the air or gas supply to about 300° C. for efficient melting of copper alloys; for iron and high temperature melting, both the gas and air should be supplied at about this temperature.

When using high-power gas, such as water gas of roughly 280 B.Th.U. value per cubic foot, n preheating is required for melting temperature up to about 1,400° C.

Tilting Furnaces *for Coke Fuel* are always of the forced draught pattern, for one their chief features, quick heating, would be greatly impaired if worked on natural draught. Th type of furnace is more efficient than the pit type, and it has the important advantage of meltin in greater bulk than can be handled in a lift-out crucible—up to ½ ton of metal at one charge- and the further advantage of making it possible to mechanically tilt the furnace on a fixed fro trunnion, so that the metal can be poured direct into ladles or moulds. In the portable patter the body portion holding the crucible can be transported by means of an overhead crane to th point at which the molten metal is wanted.

Furnaces for Oil Fuel.—The remarks made above in connection with pit furnaces appl also to the tilting pattern. The economy in oil when melting, say, ½ ton of metal in one crucib with one burner, will be very marked, compared with, say, five burners for five 200-lb. size p furnaces, and the consequent saving in power for air blowers in equal proportion.

Producer Gas can be applied to tilting furnaces as for pit furnaces, but tilting furnaces bein of greater capacity than the latter it becomes possible to run single furnaces with producer ga the heat in the waste gas being utilised to warm the incoming air or gas supply. For copp alloys it is usual only to preheat the air.

The 'Radiation' Gas-heated Furnaces.

Natural-draught Oven and Muffle Furnaces for Hardening, Case-hardening, Annealing, etc.

These furnaces are of the 'under-fired' type, and are heated by means of gas supplied a normal town's pressure, the burners being so proportioned and located under the furnace heart as to ensure even heat at the required temperature throughout the whole working chambe Each burner has separate gas taps and air adjustments. Depending on the class of work, thi apparatus can be constructed as either a muffle or oven furnace. The furnaces are frequentl constructed with two heating chambers, an arrangement which gives, without lowering tempera ture in the bottom chamber or increasing the gas consumption, a pre-heating top chambe maintained at a temperature of about 300° C. less than the lower one. Where temperature of 1,000° C. and over are required, the furnaces are used in conjunction with air-blast burners as natural-draught furnaces are not recommended above 950° to 1,000° C. The furnaces ar also capable of modification to use oil fuel as a heating medium.

Low-pressure Gas and Air Furnaces for Annealing, Case-hardening, Reheating, Hardening, and Forging, etc., etc.

This furnace is 'over-fired,' i.e. the gas supply at normal town's pressure is led through port at one or both sides, where it comes into contact with the air supplied (at approximately 2 in. w.g. obtained from a small fan, which air has been previously well pre-heated by being taken throug the opposite side of the furnace in fine clay tubes, and then passed along the bottom of furnac in close proximity to waste products. Combustion takes place inside working chamber, th flames produced keep well up and sweep round the arch. The products of combustion then pas to the opposite side of furnace, are carried under the floor and up the other side away to the flue

Patent Twin-chambered Furnaces for Hardening High-speed Steel.

This twin-chambered furnace is specially designed for the hardening of high-speed stee tools, and combines durability with economy of working. The furnace linings are of exceptiona thickness, and the doors are constructed to conserve the heat and protect the operator. The fuel in this case may be either oil or gas, and special attention has been paid in order to secure a reducing atmosphere, in consequence of which the tools can be raised to the necessary high temperature without scaling or blistering. The upper chamber is heated by the waste heat from the lower one, and is used for the preheating of tools before finally raising them to the high temperature required for hardening.

Patent Salt Bath Furnace for Hardening and Heat-treatment of Cast and Special Steels and Reheating of Mild Steel after Carburising.

This furnace is designed for very accurate control, and consists of a metal pot containing fusible salt (pyromelt), which fuses at 670° C. Suspended above this pot is a rising and falling tray, which holds the work and also acts as a stirrer when in the molten liquid. Special provision is made for a pyrometer to be inserted in the liquid, and for protecting it against damage. This apparatus is suitable for heating up to 900° C., but at this high temperature the life of the pots is uncertain. Up to this point, however, heating is under complete control, and any required treatment may be repeated with mechanical precision. The furnace may be heated by coal gas, producer gas, or oil, in conjunction with air under pressure.

Tilting Crucible Furnaces for Melting Copper, Gunmetal, Brass, Aluminium, etc.

This type of furnace is designed for use where a large quantity of metal is to be heated at ne time, and where it is important that the heat be maintained while the metal is being poured. he furnace body is constructed in wrought steel, strongly stiffened and lined with fire-brick. is mounted on trunnions and tilted by means of a hand wheel, operating bevel, and worm gears. hese latter are covered in to protect them from damage by sand, etc., and for safety. The rnace is fitted with a loose bottom plate with slag holes, and this can be removed to facilitate ie renewal of the base brick. Below the bottom plate is a loose pan, so that should a crucible reak, the molten metal runs through the slag holes and is collected, thus preventing damage burners beneath.

ELECTRIC FURNACES.

(*A. H. Allen, M.I.E.E., and Professor Owen W. Ellis, M.Sc.*)

The classification of electric furnaces has already been dealt with (pp. **2651–2652**). It mains to treat in detail of these furnaces and their application industrially.

Electric Furnaces Heated by Resistance Effects.

Those furnaces of this type in which the charge is included in the electric circuit (fig. 7) e of indirect interest only to the engineer. They are employed largely in the manufacture of minium, carborundum, calcium carbide, etc.

Those furnaces of this type in which the charge is heated by means of an electrically-heated nductor find extensive employment in laboratories, and are coming into more general use for ie annealing and thermal treatment of steel and the melting and heat treatment of non-rrous alloys.

The smaller furnaces, such as are used in laboratories, are often made after the style of gas-ated muffle furnaces, but in place of gas jets, wire of platinum or incorrodible alloy, heated by ie passage of an electric current, is wound round the body of the chamber. Another type nsists of a tube of carbon, cut into a spiral or helix, through which the current flows.

Discussing furnaces of the larger type, T. F. Baily states that a 150-kw. annealing furnace ating 1,000 lbs. of steel to 900° C. in one hour consumes 300 kw.-hours per ton. With regard melting in a shop working 24 hours per day, the following costs were recorded :—

	s.	*d.*
Electricity, 400 kw.-hours per ton at $\frac{1}{2}d.$	16	8
Metal loss, 1 per cent. zinc at 5*d.* per lb.	8	4
Labour, 1 man per 600 lbs. per hour at $\frac{3}{8}d.$ per hour .	5	0
Renewals and repairs	4	2
Total per ton of brass melted	£1 14	2

These furnaces are provided with separate heating elements of carbonaceous material, which not come into contact with the charge, but are made incandescent by the current passing rough them, and thus heat the interior of the furnace chamber.

Induction furnaces (figs. 8 and 9), which may be classed under this head, find employment the manufacture of steel. They are able to hold their own against other types of steel-melting rnaces on account of their steady current consumption and low power consumption in the melting cold stock, but suffer from certain disadvantages of a well-defined character. The heat being nerated in the metal and only conducted to the slag renders it impossible to work a fluid basic ag, with the result that desulphurisation of the charge is not so efficiently carried out as in the se of furnaces of the resistance or arc-resistance type. Nor can dephosphorisation be so rfectly attained, since the design of these furnaces militates against ready and complete removal the oxidising slag needed for the removal of phosphorus. A further disadvantage arises as result of the continuous circulation of the molten metal in the bath which leads to the erosion the lining. This, in addition to the corrosive effect of the slag, leads to high figures for lining pairs.

Were the induction furnace of more flexible character and efficient design, it should nd wide application in the melting of brass containing as high as 50 per cent. zinc. At present is type of furnace is being experimented with in the direction of non-ferrous alloy melting.

Electric Furnaces heated by Arc Effects.

Only furnaces in which indirect heating of the charge (fig. **10**) is carried out are of interest this connection. The Stassano furnace is the most striking example of this type. The power nsumption of arc furnaces is high, and fluctuations in the value of this factor are, when the rnace is being employed in the fusion of cold stock, of high magnitude.

In the melting of copper alloys the indirect arc furnace may be employed economically in rge units. For melting brass containing not more than 10 per cent. zinc it has also been used.

Electric Furnaces heated by Combined Resistance and Arc Effects.

By far the largest number of electric furnaces in use industrially are of this type. In this lass of furnace an arc is struck between the extremities of vertical electrodes and the liquid or olid furnace charge (fig. 11). In many furnaces of this type negative electrodes are built into he furnace bottom or sides so that current is forced to flow through the bath (fig. 12). In oth cases the bath is heated by (i) the heat of the arc and (ii) the heat produced by the esistance of the steel and slag to the passage of electric current.

The electrodes, which are of graphite or amorphous carbon, are capable of movement in a irection parallel to their axis and are controlled, either by hand or by electrical device, so as to etain the arc at as constant a length as may be desired either for melting, refining, heating, tc., of the metal. In certain cases the practice of completely immersing the electrode in he molten charge—thus utilising the resistance effect of the electric current only—is in vogue.

For making steel the arc resistance type of furnace is that chiefly used, the charge generally onsisting of scrap steel. The composition of electric steel can be very accurately controlled, nd the proportions of sulphur and phosphorus in the final product can be reduced to mere traces. n improvement in quality is, therefore, to be expected. The most widely used arc-resistance urnace is the Héroult, of which, according to the Society for Electrical Development, 181 were n operation on January 1, 1917, 84 of these being in the United States and Canada. These nd similar furnaces are largely used for making small castings in steel, malleable iron, and ast iron, their capacities ranging from 1 to 20 tons ; 6-ton furnaces are very common. Other ell-known furnaces of this class are the Girod, Nathusius, Keller, Gronwall, Electro-metals, nd Greaves-Erchells. Each of these furnaces is possessed of special characteristics which ppeal to individual users. While steel melting and refining, and the production of steel and ron castings, occupy the vast majority of electric furnaces, all the foregoing types can be, and ave been, used for melting brass, copper, etc., though it is questionable whether their use for uch purposes can be considered as expedient.

Arc-resistance furnaces for steel melting are most frequently lined with basic refractory naterials. Acid-lined furnaces are, however, employed, chiefly to melt down high-grade raw naterials. The necessity for utilising such materials, for which high prices must be paid, renders he mere melting process a costly one. Further, as the treatment of molten steel on an acid earth leads to an appreciable gain in those elements, sulphur and phosphorus, most to be voided, the process is still further limited in its application.

The process employed for the production of steel in basic-lined arc-resistance furnaces is letermined by (*i*) the stock on hand and (*ii*) the product desired.

Should the stock on hand be of fair quality, i.e. containing contents of sulphur and phos-horus not above 0·06 per cent., the process may consist of (*i*) the application to the charge of basic oxidising slag and (*ii*) the conversion of this slag, by means of suitable additions of coal lust and lime, into a reducing slag, which is allowed to remain in contact with the molten steel luring the operations of teeming from the furnace and of casting from the ladle. Such additions f ferro-alloys as are required to bring the steel up to the standard required are made when the lag is as completely reducing in character as is possible under the conditions imposed by practice.

If the stock on hand is of poor quality, i.e. should it consist of scrap containing high (from ·06 to 0·20 per cent.) sulphur and phosphorus, or if it is desired to specially refine stock of fair uality, the first slag—the basic oxidising slag—is removed from the surface of the steel in the urnace. The removal of this slag implies the removal of the major portion of the phosphorus rom the steel, and unless the removal be very complete a return of phosphorus to the steel may e expected, the content of phosphorus returning to the steel under these conditions being oughly proportional to the amount of slag allowed to remain upon the charge. Occasionally it may be necessary to apply a further oxidising slag to the metal in the bath ; generally, however, one slag only is made. The first slag having been removed, deoxidation and desulphurisation are effected by the medium of a slag composed largely of calcium silicate. The 'physic' required to provide for carbon, manganese, etc., in the finished steel may be added immediately after the first slag has been removed. Generally speaking, the additions are made at a later stage in the process. The complete deoxidation of the metal is made evident by the appearance of the slag, which, the above conditions prevailing, decrepitates spontaneously and is practically white when cool.

Melting and refining carried out on a basic hearth results in a practically complete loss of carbon, silicon and manganese, and a very appreciable loss of sulphur, phosphorus and such elements as chromium, molybdenum, etc.

The possible uses of the electric furnace in the steel foundry have been tabulated by J. H. Hall:—

Melt scrap	Impure: eliminate phosphorus and sulphur. Pure: get hot and cast. Alloy steels.
Melt pig and more or less scrap. Eliminate C, Si, Mn.	Impure: eliminate phosphorus and sulphur. Pure: get hot and cast.
Treat hot metal	From cupola: eliminate C, Si, Mn, S and P. From acid Bessemer or open hearth: eliminate S and P. From basic open hearth: eliminate S and P.
Melt pig and scrap and treat cupola metal	Eliminate C, P and S without loss of Mn and Si. (Greene's process.)

The arc-resistance furnace proved to be of value during the war in the preparation of high grade pig iron to replace the Swedish pig iron so much sought after for the preparation of high grade steels.

According to E. K. Scott, a 10-cwt. steel-melting furnace running 9 charges a day will do as much as 36 crucible-steel furnace holes, each accommodating two 56-lb. pots, and can be operated by one man and an ammeter boy, whereas the crucible furnaces require 15 men, most of them skilled. The electric furnace, with its transformer and switch-gear, occupies one quarter as much space as the crucible plant, and costs half as much to instal. It can deal with a charge consisting entirely of turnings, millings, etc., whilst in the crucible-steel process only a very limited quantity of turnings can be used. The renewal of the furnace linings costs less than that of crucibles for the same output. Consequently the electric-steel furnace has been largely adopted in Sheffield in place of crucible furnaces.

The chief **losses** in electric furnaces are due to radiation from the walls and conduction through the electrodes. Since the radiation losses increase as the square and the capacity as the cube of the linear dimensions of furnaces, it is obvious that large installations are more economical than small ones. Conduction losses can be reduced to a minimum by suitably designing the electrodes.

Although, with coal at 14*s.* per ton and electrical energy at ½*d.* per kw.-hour, the latter costs twenty-eight times as much as the former per British thermal unit purchased, the efficiency with which the electrical energy is applied is so much higher that the difference is largely neutralised, and in the case of crucible steel is completely wiped out. In addition, the labour cost is greatly reduced with electric furnaces and there is a considerable economy of space and buildings, while the steel produced is of higher quality and uniformity than by any other method.

A useful method of calculating heat flow through the furnace walls, etc., has been developed by Carl Hering on the lines of Ohm's law. If—

W = heat flow in watts; T = drop in temperature in degrees C.; R = thermal resistance in 'thermal ohms,'

then,

$$W = T/R.$$

A thermal ohm is that thermal resistance which requires a drop of temperature of 1° C. to produce one watt of heat flow and = 4·2 gramme-calorie units; 1 gramme-calorie unit of thermal resistance = 0·24 thermal ohm.

Assuming that the electrodes are of uniform section, and that no lateral loss of heat takes place—conditions which are only approximately fulfilled in practice—Hering finds that the total loss of heat through the cold end of the electrode equals the sum of the loss by heat conduction alone (i.e. when no current is flowing) and half the T^2R loss. This combined loss is least when the loss by heat conduction alone equals half the T^2R loss; the total loss then equals the T^2R loss, and no heat will be conducted out of the furnace by the electrodes. This minimum loss is dependent only on the material of the electrodes, the current, and the temperature, but not on the absolute dimensions; it fixes the ratio of cross-section of electrode to length. In the case of a furnace working at 1,400° C., the cool end of the electrode being at 100° C., the length of the electrode 20 ins., and the current 10,000 amperes, the following dimensions were given by Hering's method of calculation:—

Carbon, 12·5 ins. diameter, loss of power in electrode 23·4 kw.; Graphite, 7·1 ins. diameter, loss of power 15·1 kw.; Iron, 4·8 ins. diameter, loss of power 4·6 kw. (*Stansfield.*)

F. T. Snyder states that in the case of a furnace melting 1,000 tons of steel a month, the cost of renewing the electrodes, plus the cost of the heat conducted out of the furnace by them, represents an expenditure of some 1,200*l.* a year per electrode. Hence the type of furnace having

.e fewest electrodes has an advantage in this respect. By using the metal bath as one terminal the arc, a furnace can be operated with one carbon electrode per arc. The furnace lining :omes conducting at very high temperatures, and this fact limits the voltage between two ectrodes passing through the same roof to a maximum of 110 volts to avoid serious leakage of irrent. The bulk of the cost of renewing refractory linings is due to roof wear round the ectrodes, and for the size of furnace above mentioned can be kept down to 800*l.* per annum per ectrode. The higher the power input the quicker is the heating and the greater the efficiency the furnace. With three electrodes the limit of power is soon reached, owing to lack of room space the electrodes sufficiently far apart to prevent current leakage through the roof lining, it with a single electrode there is no such limit to the power input.

The power, etc., provided in connection with Héroult furnaces used by the United States eel Corporation are given in the following table, which applies to cold charges; if the charge put into the furnace in a molten condition about half this power suffices :—

POWER REQUIRED FOR ELECTRIC FURNACES.

Size of Furnace, tons.	Transformer capacity, kva.	Amperes, per phase.	Square inches Copper, per phase.
1	375	2,250	3
2	600	3,600	5
3	750	4,500	6
4	900	5,400	7
6	1,200	7,200	9
10	2,000	12,000	16
15	3,000	18,000	24

The voltage used in arc furnaces depends upon the current and the length of the arc. In ree-phase furnaces it ranges between 75 and 100 volts, and in single-phase furnaces between 0 and 200 volts. In resistance furnaces the voltage at starting, with a cold charge, may be 0 volts, decreasing as the charge heats up to 35–60 volts. The consumption of the electrodes ries widely according to the conditions obtaining, from 3½ to 20 lbs. per ton of steel produced. ie furnace bottoms last from 1 to 3 years, the walls from 100 to 300 heats, and the roof from to 200 heats. To make ordinary carbon steel of crucible quality with a 6-ton furnace requires)m 550 to 750 kw.-hours per ton, starting cold. In smaller furnaces the input per ton is eater. The following figures for a Rennerfelt furnace are due to C. H. Vom Baur.

ENERGY REQUIRED IN TREATING VARIOUS METALS.

	Kw.-hours
Melting red brass	168
„ pure copper	197
„ white iron	280
„ gray iron	325
„ 80 per cent. ferro-manganese	441
„ and refining steel scrap on a basic bottom	700

The power factor of the arc resistance furnace varies from 85 per cent. to more than 90 per it.; that of the resistance type from 90 to 97 per cent.; that of the induction furnace varies)m 50 to 60 per cent. only.

The efficiency of a Héroult furnace was tested with a charge consisting of 5,733 lbs. steel ap, 430 lbs. iron ore, 346 lbs. lime. The input was 215 kws. for the first hour, at 110 volts, and erwards 342 kws. The total time taken to melt the charge was 5⅓ hours, and the total ergy input for melting was 1,680 kw.-hours. The ratio of heat utilised to heat supplied (the iciency) was 76·5 per cent. The time required for the purification and carburisation of the el was 3 hours, and the result was 5,161 lbs. of tool steel. The total consumption of energy s 2,580 kw.-hours, or 0·171 e.h.p.-year per ton of steel.

The leads from transformers to electric furnaces should be as short and direct as possible, and se together, as the voltage drop due to their self-inductance and the very large currents is con-erable, resulting in a low power factor. The conductors should be wide thin bars, or tubes, to vent loss of energy due to the tendency of alternating current to flow in the skin of the nductor.

ELECTRICAL RESISTIVITY OF MATERIALS, OHMS PER INCH CUBE.

Material.	Cold.	Hot.	Temperature ° C.
Graphite	0·00034	0·00031	100–2000
Carbon	0·0018	0·0014	100–2000
Silicate slag	∞	1 to 2	Molten
Fire bricks (various)	∞	8 to 24	850
		24 to 300	815

(*Stansfield.*)

FURNACE CONSTRUCTION.

The following are points requiring special attention in the construction of furnaces :—

1. Sections of furnaces such as are exposed to differing physical and chemical actions shoul be united in such a manner as to allow of free and independent movement and as to be subjec to independent condition.

2. Such sections as are exposed to high temperatures should be made thin and should, whe possible, be water-cooled; such sections as are exposed to low temperatures should be mad of such a thickness as will reduce thermal losses due to radiation and conduction to a minimun

3. The interiors of furnaces should be constructed so as to resist mechanical, physical an chemical wear. With this end in view choice must be made of suitable materials of constructio and of efficient design. In this connection note should be made of the following factors :—

(*a*) The action of heat.
(*b*) The erosive and corrosive actions of flame, slag, etc.
(*c*) The mechanical wear due to abrasion by the solid charge, etc.

4. The exteriors of furnaces should be supported and strengthened in such a way as to allo of the free expansion and contraction of the body. The foundations of all furnaces must be of strong and rigid character.

MELTING POINTS OF REFRACTORY MATERIALS.

	° C.
Alumina (pure)	2010†
Bauxite	1820†
Bauxite brick	1565 to 1785†
Bauxite clay	1795†
Chromite	2180†
Chromite brick	2050†
Fireclay brick—Highest grade	1843*
General grade	1650 (average)*
Ditto	1649 (average of 41 samples)†
Ganister	1700 to 1800
Kaolin	1735 to 1740†
Magnesia brick	2165
Silica—Pure	1750†
Pure	1830*
Pure, with 14·5 per cent. alumina	1690*
Pure, with 63·0 per cent. alumina	1890*
Brick	1700 to 1750†

The melting points have been considered to be those temperatures at which the material i question was first seen to flow easily.

* Boudouard.
† Kanolt—'Iron and Coal Trades Review,' vol. lxxxv. p. 309.

FURNACE EFFICIENCY.

The thermal efficiency of furnaces may be stated either absolutely or relatively :—

$$\text{Absolute furnace efficiency} = \frac{\text{Net thermal effect produced}}{\text{Calorific power of the fuel}}.$$

$$\text{Relative thermal efficiency} = \frac{\text{Net thermal effect produced}}{\text{Actual calories realised}}.$$

Owing to the large variation in the actual number of calories realised in individual furnaces it is general to employ the former of the above ratios. In order that a determination of the absolute efficiency of a given furnace may be made, a knowledge of the heat-absorbing and the heat-producing factors that are likely to be encountered in practice, of which a number are tabulated below, is required.

(*A*) Heat-absorbing Factors.

1. Heat absorbed by fume, gases, etc.
2. Heat removed by such solids and liquids as are periodically or continuously removed from the furnace.
3. Heat lost by radiation and conduction.
4. Heat absorbed owing to endothermic reactions within the furnace.

(*B*) Heat-producing Factors.

1. Heat supplied to the furnace by the combustion of fuel either inside or outside the furnace.
2. Heat added by such solids and liquids as are periodically or continuously charged into the furnace.
3. Heat gained owing to exothermic reactions within the furnace.

The thermal efficiency of the furnace is represented by the ratio of the heat-absorbing factors to the heat-producing factors.

Heat Economy by Insulation.

A considerable reduction in the loss of heat by radiation (see *A*, 3, above) may be effected by building a 'wall' of insulating bricks (p. 537) between the lining and the exterior of the furnace.

Latent Heat of Fusion of Metals.

The latent heat of fusion is the number of gram calories required to convert one gram of substance from solid into liquid without change of temperature :—

Mercury	2·8 calories.	Platinum	27·1 calories.
Lead*	5·5 ,,	Sodium	31·7 ,,
Bismuth*	10·2 ,,	Palladium	36·3 ,,
Cadmium*	10·8 ,,	Manganese*	36·7 ,,
Tin*	13·8 ,,	Antimony*	38·9 ,,
Potassium	15·7 ,,	Copper	41·0 ,,
Gold*	15·9 ,,	Nickel*	56·1 ,,
Iron	(See note).	Cobalt*	58·2 ,,
Silver*	26·0 calories.	Aluminium*	94·0 ,,
Zinc*	23·0 ,,		

NOTE.—The latent heat of fusion of iron as determined by Campbell (and confirmed by Oesch) from freezing-point depression data is 20·1. C. Brisker (1908), as a result of an examination of Carpenter and Keeling's freezing-point determinations of the iron-carbon system, has arrived at the value 31·6 for this element. Grumer gives values of 23 and 33 for gray and white cast iron respectively. Wüst obtained the value 49·4 for this factor.

Heat and Electrical Energy required for Fusion of Metals.

The following table (after Stansfield) gives the heat and electrical energy required to melt various metals, per lb. :—

	Calb.†	Watt-hours.		Calb.†	Watt-hours.
Tin	28	15	Copper	162	85
Lead	16	8	Cast iron (gray)	245	129
Zinc	68	36	Tool steel (1 % C.)	300	158
Aluminium	258	136	Wrought iron	343	181
Brass	130	69			

(See also p. 2665.)

* Values after Wüst. *Stahl und Eisen*, 1918, 38, 177.

† *Calb.*—The amount of heat required to raise one pound of water through one degree Centigrade.

Calorie.—The amount of heat required to raise one gram of water through one degree Centigrade.

TEMPERATURE CONTROL OF FURNACES—PYROMETRY.

Determination of Calorific Intensity.

The calorific intensity of a substance is the theoretical maximum temperature attained during the perfect combustion of the same in air at 0° C. and 760 mm. pressure, and is inversely proportional to the time occupied in attaining to this temperature. The calorific intensity of a substance may be determined by calculation or by experiment.

Calculation.

Let C = the calorific power of the substance,
T = the rise in temperature during combustion,
$w, w', w'', \ldots$ = the weights of the products of combustion,
$s, s', s'', \ldots$ = the specific heats of the products of combustion,

then,

$$T = \frac{C}{ws + w's' + w''s'' + \text{etc. etc.}}$$

for the fuel at 0° C. and 760 mm. pressure.

The calorific intensity of a fuel (by formula) will be seen to be directly proportional to the calorific power of the fuel and inversely proportional to the weights and the specific heats of the products of combustion.

The calorific power can be raised by

(*a*) Superheating the fuel.
(*b*) Superheating the air needed for the combustion of the fuel.
(*c*) Using a minimum of excess air.
(*d*) Increasing the proportion of oxygen in the air.
(*e*) Reducing the proportion of incombustible material in the fuel.

Experiment.

The calorific intensity of a fuel may be determined by experiment. For the purpose in question a variety of instruments has been designed, almost every thermal property of matter having been employed as a basis for the construction and calibration of these instruments, which are generally known as pyrometers.

Reference may be made to the Bulletin of the United States Geographical Survey, No. 54 (1889), where the following classification of the properties on which the construction of pyrometers has been founded is given :—

1. Dilatation of solids:
   (*a*) A single solid.
   (*b*) Two solids acting differentially
2. Dilatation of liquids.
3. Dilatation of gases:
   (*a*) Expansion measured in volume, manometrically.
   (*b*) Expansion measured in pressure, manometrically.
   (*c*) Expansion measured in volume, by displacement.
4. Vapour tension.
5. Dissociation.
6. Fusion.
7. Ebullition.
8. Specific heat.
9. Heat conduction.
10. Heat radiation.
11. Viscosity:
    (*a*) Of solids.
    (*b*) Of liquids.
    (*c*) Of gases.
12. Spectrophotometry and colour. Rotary polarisation.
13. Acoustics (wave length).
14. Thermo-electrics.
15. Magnetic moment.
16. Miscellaneous.

Expansion Type Thermometers.

The mercurial thermometer is most important for use at about atmospheric temperatures, largely on account of the wide range of temperatures through which mercury is liquid, —39° C. to 357° C. If a high-grade mercurial thermometer has been calibrated at the National

Physical Laboratory, it is possible to measure temperatures throughout its range to an accuracy of 0·001° C. By the use of inert gases (nitrogen or carbon dioxide) under pressure in the tube of a thermometer, the boiling point of the mercury may be raised to allow temperatures up to 540° C. to be determined, at which temperature the glass softens. Quartz thermometers containing mercury under pressure can be used up to 700° C. By using tin instead of mercury the maximum limit may be raised to 1000° C. Steel tube mercurial thermometers, in which the capillary is attached to a form of a Bourdon pressure gauge, are not easily broken, and may be relied upon up to 540° C.

Fusion Pyrometers.

Observations of the fusion of metals, alloys, salts or mixtures of salts enable the observer to judge the temperature reached in a furnace at the moment of fusion, given that the temperature of fusion of the material employed is known prior to its introduction into the furnace. Fusion pyrometers are most suitable for the registration of maximum temperatures, after the attainment of which the source of heat may be eliminated and the furnace or heated object allowed to cool.

Metals.

The base metals have the disadvantage of ready oxidation; the precious metals offer only a limited number of definite temperatures.

Alloys.

Only eutectic alloys (see p. 2674) and solid solutions (see p. 2674) are of value. Base metal alloys being subject to oxidation, only precious metal alloys remain as suitable fusion pyrometers. Both the alloys of silver and gold and those of gold and platinum have been employed for pyrometric work, the latter, according to Séger, being satisfactory up to a temperature of 1200° C. only.

Salts.

The following are the melting points of a number of metallic salts that have found use in pyrometric work :—

Salt.	Melting Point.	
Calcium nitrate	561° C.	1042° F.
Strontium nitrate	570 ,,	1058 ,,
Barium nitrate	593 ,,	1099 ,,
Potassium iodide	705 ,,	1301 ,,
Potassium bromide	750 ,,	1382 ,,
Potassium chloride	790 ,,	1454 ,,
Sodium chloride	800 ,,	1472 ,,
Sodium carbonate	849 ,,	1560 ,,
Sodium sulphate	880 ,,	1616 ,,
Barium chloride	960 ,,	1760 ,,
Potassium sulphate	1050 ,,	1922 ,,

Mixtures of Salts.

Under this heading may be included two important types of fusion pyrometers :—

(*a*) Séger cones.
(*b*) Sentinel pyrometers.

Séger Cones.

These are small three-sided pyramids, each about 2½ ins. high and about ½ in. wide at the base. The term 'cone' is rather misleading, as they are more pyramidal than conical. They are made of a finely ground mixture of felspar, china clay, and flint, the composition of the mixture depending on the temperature to be indicated. For the lower members of the series other mixtures are used

These cones were invented by the late Dr. Séger of Berlin, in order to provide some means of recording the effect of heat on various porcelains. Their shape and composition are such that when heated to their indicating temperature at a reasonably slow rate and under suitable conditions they bend over slowly from the upright position possessed by them when placed in the kiln or oven and gradually form an arch. When the top has almost reached the same level as the base the indicating temperature is reached. A further rise in temperature will cause the cone to collapse and form a shapeless, glazed mass.

It is customary to employ three different cones at a time; the first will indicate a temperatur about 20 degrees Cent. below the one required to be known, the second cone will indicate th desired temperature (such as the finishing temperature of a glaze) and the third cone will serv as an indicator that the required temperature has not been exceeded by 20 degrees. The com position of the cones is such that the difference in temperature shown between two successiv cones is about 20 degrees, though they are not quite regular in this respect.

It is important to remember that Séger cones do not serve as strict indicators of temperatu in the sense that a thermometer does. If heated too rapidly a much higher temperature may b reached than is normally required to bend a cone, and which they are supposed to indicate. Unde ordinary conditions of use, however, it is easy to find which cones correspond to the temperature or conditions of heating which it is required to control, and Séger cones are, therefore, invaluabl when they are rightly used. They serve as excellent indicators of the effect of heat on potter and similar materials, and as it is this, rather than the mere momentary temperature which i important, they have advantages not possessed by a pyrometer or high temperature thermomete

They were originally made only at Dr. Séger's laboratory in Berlin, but since 1914 they hav also been made at the Pottery School, Stoke-on-Trent, and sold by Messrs. Keeling & Walke Sutherland Mills, Stoke-on-Trent.

Owing to their cheapness and the difficulty of ensuring their accuracy when made by amateur it is usually better to purchase the cones rather than to attempt to make them.

The following temperatures are those nominally associated with Seger cones, but, as explaine above, it is preferable to refer to the number of the cone rather than to the temperature.

SÉGER CONES AND TEMPERATURES.

Séger Cone.	Deg. Cent.	Deg. Fah.	Séger Cone.	Deg. Cent.	Deg. Fah.	Séger Cone.	Deg. Cent.	Deg. Fah.	Séger Cone.	Deg. Cent.	Deg. Fah.

SENTINEL PYROMETERS.

These are small cylinders, measuring about $\frac{3}{4}$ in. by $\frac{1}{2}$ in. and manufactured from salt ixtures of definite melting points. Only such mixtures can be utilised as are formed of salts that ither dissociate nor corrode when in the molten state. Brearley states that 'mixtures of salts, ter being melted together and ground to a very fine powder, may be made into an adhesive paste th vaseline, and applied to many purposes for which no ordinary pyrometer is available. In the nith's hearth, for example, a tool may be heated to low redness and smeared near the point th a small portion of a paste whose melting point is, say, 770° C. The tool is then reheated rectly in the fire or protected from the coke by a piece of scrap, wrought or cast iron piping, until e white mark left by the thin layer of the salt mixture disappears. This indicates that the steel lf has nearly reached the desired temperature and may be quenched.'

The following are the melting points of a number of mixtures of salts:—

Salt.	Parts by Weight.	Salt.	Parts by Weight.	Deg.
Potassium carbonate .	50	Potassium chloride	50	580 C.
Sodium chloride . .	30	Ditto	70	625 C.
Ditto	42	Ditto	58	655 C.
Potassium sulphate .	20	Sodium sulphate	80	825C.
Ditto	30	Ditto	70	830 C.
Ditto . . .	50	Ditto	50	850 C.

Heat Radiation Pyrometers.

In this type of instrument the relation between the effect of radiant heat on suitably chose thermal elements and the temperature of the radiating body is observed. The Féry Radiatic Pyrometer is an example of this class of instrument.

In this pyrometer the rays from the hot body are received on a concave mirror, which can s be adjusted that the rays form a heat image which covers a small sensitive element permanent fixed on a line through the axis of the mirror. The sensitive element consists of a delicate adjusted thermo-couple, which delivers current to a millivoltmeter, calibrated, if desired, read the temperature of the body, whence the heat rays are emanating, directly. In both cas suitable means are provided for ensuring that the sensitive element is completely covered by t image of the radiant body.

In order that correct results may be obtained when using pyrometers of the radiation type it necessary that the hot body sighted should be enclosed within a vessel whose walls are approx mately at the same temperature as the body itself. If this precaution is not observed the readi obtained will be lower than the true temperature of the body, the degree of inaccuracy bei dependent almost entirely on the nature of the surface of the body in question.

Optical Pyrometers.

Approximate estimations of the temperatures of incandescent bodies may be made by visu observation. Numerous colour scales have been proposed, but those due to Howe and Taylor a White are generally accepted as the most accurate. The following table (based on one by How is of value in this connection.

Taylor and White.		Howe.	
Name of colour.	Degrees C.	Name of colour	Degrees C.
—	—	Lowest visible red in the dark	470
—	—	Lowest visible red in daylight	475
Dull red, blood red, low red	566	Dull red	550–625
Dark cherry red	635	—	—
Cherry, full red	746	Full cherry	700
Light red, bright cherry, light cherry	843	Light red	850
Orange	899	—	—
Light orange	941	—	—
Yellow	996	Full yellow	950-1000
Light yellow.	1079	Light yellow.	1050
White	1205	White	1150

The design of optical pyrometers is dependent on the fact that the intensity of the light ray emitted from an incandescent 'black body' is directly proportional to the temperature of the 'body

The Mésuré and Nouel Pyrometric Telescope consists of two suitably mounted Nicol prisms, s adjusted that their planes are at right angles to one another when the scale of the instrument is a zero and between which is placed a quartz plate cut perpendicularly to its axis. When the incand escent body is observed through the instrument it is necessary to rotate one of the Nicols in orde to extinguish the emitted light. The angle of rotation is proportional to the thickness of the quart plate, which is a constant for any given instrument, and inversely proportional to the square roo of the wave length of the observed light. The wave length of the observed light being proportiona to the intensity of the light, the angle of rotation of the analyser or polariser is a measure of th temperature of the incandescent body.

The Cornu-Le Chatelier Photometric Pyrometer is designed to measure the intensity of th light emitted by an incandescent body by reducing this intensity until it corresponds to tha of the light emitted by a standard lamp. The reduction required is inversely proportional to th temperature of the hot body.

The Wanner Photometric Pyrometer likewise compares the intensities of the lights emitted by the incandescent body and a standard body respectively. In this instrument, however, spectr of the two sources of light are, firstly, broken up into two polarised planes at right angles to on another; secondly, adjusted so that only the narrow red bands of each spectrum are transmitte

rther; and, thirdly, so brought into vision that the intensity of either field, both being in visual ontact, can be strengthened or weakened, until they are equally intense, by rotation of a Nicol rism. The amount of rotation, which can be observed on a suitably situated scale, serves to ieasure the intensity of the emitted light, and hence to define the required temperature.

The Cambridge Optical Pyrometer is, in principle, the same as the foregoing, and is invaluable or temperature measurements between 700° and 4000° C.

Thermo-Electric Pyrometers.

This type of pyrometer is dependent for its action upon the fact that a current is produced vithin a closed circuit formed of two dissimilar metals when the junction between the two metals is eated, the current being proportional to the absolute temperature of the junction.

The essential features of this pyrometer are two thin insulated rods or wires of dissimilar ietals coupled at one of their ends and connected at their other ends to separate leads. The onnection between the two metals and the leads, which is known as the 'cold-junction,' is nclosed within suitably designed apparatus that can be retained at a known constant tempe- ature. The leads from the 'cold-junction' pass to some form of electrical instrument capable f registering or recording changes in the P. D. produced in the now closed circuit when the hermo-couple is heated or cooled.

The number of metals and alloys available for the manufacture of thermo-couples are few. The ollowing are among those most generally employed :—

Couple.	Range.
Platinum—platinum rhodium	Up to 1400° C.
Platinum—platinum iridium	„ 1000 „
Nickel—nickel chromium	„ 800 „
Silver constantan	„ 600 „
Copper constantan	„ 500 „
Iron constantan	„ 500 „

For the estimation of temperatures above the melting-point of platinum the iridium-iridium- uthenium couple has been suggested, but it is considered unlikely that the same would prove fficient, on account of the known volatility of iridium at such temperatures.

Union between couple *wires* is effected by fusion in the electric arc or oxyhydrogen flame n the case of couples having a platinum base, by soldering or brazing in the case of base-metal ouples or by twisting. Union between the wires and the leads can be effected as above or by ieans of electrical clamps.

The couple wires, when in use, are generally protected by tubes of nichrome, fireclay, silica r glazed porcelain, the last being particularly useful when it is desired to defend the wires gainst the deleterious action of hot gases. When necessary, protection is afforded these tubes y enclosing them in steel jackets.

Heavier types of thermo-electric pyrometers consist of a *rod* of one metal fitted tightly into ne end of a cylinder concentric with the rod and of another metal and insulated from the same y suitable means.

Calibration of thermo-electric pyrometers is effected by immersing the protected couple in ubstances or the vapour of substances whose melting or boiling points are known. The couple, eing subject to like thermal changes as the substance, causes a fluctuation in the current flowing vithin the closed circuit, which fluctuation is registered by the instrument within the circuit. For example, while solidification of a metal in which the protected couple is immersed is in progress constant reading is obtained on the instrument. This value is observed, and is recorded on a graph against the melting point of the metal as ordinate. A series of such points may be btained by employing a number of metals in similar manner to that already described, and, hese points being united, a curve is obtained from which the temperature corresponding to any iven reading of the instrument may be abstracted.

The following are the melting points on the thermo-dynamic scale used by the Washington Bureau of Standards as standard temperatures in the standardisation of thermometers and yrometers :—

Mercury	— 38·9° C.	Antimony	630·0° C.	Nickel	1452° C.
Tin	231·9 „	Aluminium	658·7 „	Iron	1520 „
Cadmium	320·9 „	Silver	960·5 „	Palladium	1549 „
Lead	327·4 „	Gold	1063·0 „	Platinum	1755 „
Zinc	419·4 „	Copper	1083·0 „	Tungsten	3000 „

At temperatures of 1000° C. the error is of the order of 0·1° C., at the melting point of platinum 5° C., at that of tungsten 100° C. A further table of other standard temperatures is given in which the following are included :—Normal boiling-point of oxygen 180·0°, sublimation of carbon

dioxide in an inert liquid 78·5°, normal boiling point of water 100°, of naphthalene 217·96°, of benzophenone 305·9°, of sulphur 444·6°, freezing point of sodium chloride 801° C.

In the *Physical Review* the melting point of rhodium is estimated to be at 1907 or 1968° C. and that of iridium as 2292 or 2388° C. That of silicon is placed at 1434 or 1452° C. and that of palladium at 1548 or 1576° C. The reason for the two figures is due to the fact that the calculations are based on different estimates of the melting-point of platinum, which has been placed at 1745° C. by some experimenters and at 1789° C. by others.

Electric Resistance Pyrometers.

In these instruments advantage is taken of the change of resistance of a wire with temperature. Platinum wire is generally employed. The essential features of the commercial apparatus are a coil of fine platinum wire, enclosed in a suitably designed protecting tube, a cell or accumulator for the supply of current to the wire and an indicator or recorder on which the temperature may be read off directly.

In the original type of this instrument errors due to the residual strain and impurities in the lead wires entered, but later instruments are designed with 'compensating wires,' whose component parts are equal in resistance to and are so arranged that they are heated to the same temperature as corresponding parts of the lead wires. Changes in resistance in the lead wires are compensated by equal changes in the 'compensating wires.'

The resistance pyrometer (after Callendar) is represented diagrammatically in fig. 13.

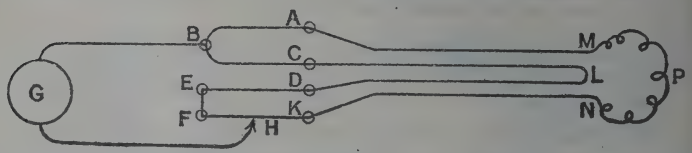

FIG. 13.

P represents the pyrometer coil; AM, KN the lead wires; CL, DL the 'compensating wires'; FK a bridge wire with scale, so arranged that 1 cm. length of the same corresponds to 1° C. rise or fall of the temperature, H the sliding contact piece, and G a galvanometer. AB and BC are wires of equal resistance. DE represents a set of resistance coils. In practice AB, BC and DE can be replaced by a post office box. Balance is obtained by the adjustment of the resistances in DE and the sliding of the contact piece H. The resistance of the pyrometer coil is given by the sum of the coils DE and the bridge wire scale reading.

Resistance pyrometers are accurate from 0° C. to 1000° C., and are employed industrially wherever reliable measurement is essential. They suffer owing to their high first cost and their fragile character. There are, however, large numbers of this type of pyrometer in use commercially.

METALS AND ALLOYS.

ALLOYS.

There are three well-recognised types of alloys:—

(i) Conglomerates of metals, or of metals and non-metals.
(ii) Homogeneous mixtures of metals, or of metals and non-metals.
(iii) Inter-metallic compounds, or compounds of metals with non-metals.

(i.)

In this type of alloy the component elemens or their compounds crystallise out from the molten alloy in a practically pure state, and the addition of one component to the other results —within certain limits—in a lowering of the solidifying point of the resulting alloy. The alloy having the lowest solidifying point in such a series is called the 'eutectic.' Lead-tin alloys are of this type.

(ii.)

In this type of alloy the component metals do not crystallise out from the molten alloy in the pure state, but contain on freezing more or less of each other in solid solution. Copper-nickel alloys are of this type.

(iii.)

Inter-metallic compounds behave similarly to pure metals, crystallising in like manner. Copper and zinc form a compound Cu_2Zn_3, which is extremely hard and brittle.

IRON.

IRON (FERRITE).

Chemically pure iron is not an article of commerce at the present time. Iron has been obtained by electrolytic deposition of a degree of purity greater than 99·9 per cent. iron, while the American Rolling Mills Co. manufacture a commercial product which they claim to contain 99·84 per cent. of iron.

Stead, by extrapolation, has arrived at the following figures for the approximate mechanical properties of pure unworked iron :—

Yield point	9 tons per square inch.	Elongation	51 per cent. (length/area = 8).
Maximum stress	17 ditto.	Reduction in area	84 per cent.

The term ' Ferrite ' is applied to pure iron when it is considered as a microscopical constituent of iron or steel. Pure iron is composed of polyhedral crystallites of ferrite.

Carbon, manganese, silicon, sulphur, phosphorus, arsenic, molybdenum, etc., all have effect on the iron in which they occur and are frequently added with a view to obtain alloys having more or less definite physical and mechanical properties.

INGOT IRON.

' Ingot Iron ' is the generic name of a commercially pure iron produced under patents owned by the International Metal Products Company. The manufacture of the metal in Great Britain is controlled by The Armco International Corporation, which company also undertakes the sale of the metal in various forms throughout the world, through suitable agents and representatives.

Ingot Iron, unlike Puddled Wrought Iron, is produced in the basic open-hearth furnace, and in view of a certain amount of difficulty in finding an acceptable definition of ' iron ' and in differentiating between ' iron ' and ' steel,' it is well to quote the definitions advanced by Dr. Albert Sauveur, who recently received the Bessemer Medal given by the British Iron and Steel Institute Dr. Sauveur says :—

' COMMERCIAL IRON is the element iron as pure as it can be commercially produced.

' INGOT IRON is commercial iron which has been produced in a fluid condition and cast.

' WROUGHT IRON is a ferrous metal which is malleable and which has been produced from a pasty condition.

' STEEL is an alloy of iron and carbon which is malleable, usually containing substantial quantities of manganese.'

'ARMCO ' INGOT IRON is ingot iron produced in the open-hearth furnace containing less than 0·02 per cent. carbon and less than 0·035 per cent manganese.

' Armco' Ingot Iron possesses many special characteristics, some or all of which will appeal to fabricators and users in many industries. The principal points of merit are as follows :—

Chemical Purity.—' Armco ' Ingot Iron contains less than one-sixth of 1 per cent. of impurities considering silicon, sulphur, phosphorus, manganese, carbon, copper, and the gases oxygen, hydrogen, and nitrogen.

Uniformity.—The method of manufacture of Ingot Iron and its freedom from impurities ensure uniformity of analysis ; this, coupled with the fact that the metal is free from slag inclusions, such as exist in even the best puddled irons to a greater or lesser degree, ensures mechanical uniformity.

Corrosion Resistance.—The conclusion that pure iron resists rust is not merely derived from theoretical inference, but represents the definite finding of many observers of the problems of corrosion, after fully investigating generations of service evidence in the form of old hand-wrought irons, such as, for example, the Iron Pillar of Delhi. These old irons were not rustless, but they resisted rust and corrosion to a remarkable degree, by reason of their freedom from corrosion-promoting impurities.

Workability.—Ignot Iron being a dense, ductile, and uniform metal, possesses exceptional working qualities.

Welding Properties.—The superior welding qualities of Ingot Iron are due to its purity and homogeneity. Being of perfectly even texture and density throughout, it welds evenly and easily.

Paint-Holding Surface.—It has been found in service that Ingot Iron sheets require painting less often than other iron and steel sheets. This is partly explained by its velvety surface, which grips and holds paint tightly, and partly by the degasification which the metal undergoes during manufacture, thereby reducing to a minimum occluded gases which in course of time tend to become liberated, and cause flaking of the paint film.

Enamelling Properties.—'Armco' Ingot Iron constitutes (it is claimed) the best base known for vitreous enamelling, for the following reasons:—

It is chemically and mechanically uniform.

Its velvety surface grips and holds the vitreous coating.

Its degasification during manufacture reduces the risk of pinholes, blisters, and other blemishes to a mimimum.

It shows less tendency to warp than other ferrous metals during the vitreous process.

Electrical Properties.—'Armco' Ingot Iron possesses a high magnetic permeability and low retentivity. It is further a better conductor of electricity than steel; in this connection the following is the result of tests undertaken by the National Physical Laboratory:—

Resistivity

By relative mass = 5·43. By relative volume = 6·17.

(Compared with the British standards for soft copper.)

This superiority in electrical conductivity renders the metal specially suitable for telegraph wire, bond wires, conductor rails, etc.

INGOT IRON can be supplied by *The Armco International Corporation* in the form of black and galvanised sheets, plates, billets, bars, shapes, wire, rods, welding rods, cold rolled strip, and welded tubes.

WROUGHT IRON.

Wrought iron is iron low in carbon content, which in course of production is in a pasty condition, owing to the fact of its being worked at a temperature too low to render it fluid. It contains a relatively large percentage of non-metallic impurities in the form of slag, which may be readily seen when the iron is examined microscopically, and which, therefore, serves, among other features, to distinguish this product from steel. The percentage of carbon in wrought iron rarely exceeds 0·15 per cent., and the total of other elements present in the metal is generally less than 0·25 per cent. Wrought iron is not appreciably hardened by quenching.

The fracture of wrought iron is fibrous in appearance and is occasionally characterised by the presence of somewhat large proportions of non-metallic inclusions.

WROUGHT-IRON (*or Mitis*) CASTINGS.

If a small amount of aluminium is added to a charge of wrought iron which has been heated until pasty, the iron immediately liquefies, and can be poured into castings having all the properties of wrought iron except fibre, and as sound as if of cast iron. These castings are called 'Mitis' castings because of their softness in contrast with cast-iron castings.

The best results are obtained by using Swedish scrap iron or English hematite iron, that is, materials containing less than 0·1 per cent. of phosphorus, which is a very injurious ingredient if present in much larger quantity. Using a mixture with poorer quality of iron, with phosphorus running up to 0·15 per cent., good results may still be obtained—that is, the castings still compare favourably with ordinary malleable castings. The following mixture for melting has been used:—Mitis scrap, 35 per cent.; hematite muck bar, 35; wrought-iron punchings, 12⅜; soft steel scrap (0·1 per cent. carbon), 12⅜, white pig iron, 3; ferro-silicon (10 per cent. silicon), 1; ferro-aluminium (6 per cent. aluminium), ⅜.

In general it may be said that if iron free from impurities is used very good castings are obtained; if iron is used with a large percentage of phosphorus, proportionately brittle and unsatisfactory castings result.

The ferro-aluminium used should be, for similar reasons, free from any considerable amount of such impurities as generally injure wrought iron.

PIG IRON.

Typical Analyses of Pig Iron, etc.

The following list of analyses is taken from Dr. W. H. Hatfield's book, 'Cast Iron in the Light of Modern Research.' It is published with the kind permission of the author and of the publishers, Messrs. C. Griffin & Co. Ltd.

CAST IRON.

Foundry Practice.

1.

The physical and mechanical properties of the products of the cast-iron foundry are almost entirely dependent on the condition of the carbon in these products. The carbon in cast iron can occur either in a free state, as graphite, or in combination with iron, as a carbide of iron, Fe_3C, or with iron and manganese, as a double carbide $(Fe, Mn)_3C$. Foundry practice consists almost entirely of the control of the degree of graphitisation of the carbides present in the cast iron produced.

The graphitisation of these carbides tends to increase—

(*a*) With the temperature.
(*b*) With deceleration of cooling.
(*c*) With the content of silicon, nickel, or aluminium.
(*d*) With the number of graphite nuclei in the iron.
(*e*) With the total content of carbon

Graphitisation is prohibited—

(*a*) By the presence of sulphur, oxygen, vanadium, or chromium.
(*b*) By the presence of manganese under certain conditions.
(*c*) By acceleration of cooling.

It will be seen that by the variation of the above factors an immense number of conditions can be obtained. It is in the scientific control of these that much of the success in foundry practice lies.

2. The Influence of Carbon on Cast Iron.

The strength, hardness, density of structure, etc., of cast iron are dependent almost entirely on the relative quantities of carbide and graphite in the same.

An increase in the ratio $\frac{\text{Carbide}}{\text{Graphite}}$ leads to—

(*a*) An increase in hardness, brittleness, and density of structure.
(*b*) A decrease in machinability and ductility.

The strength of cast iron reaches a maximum when the combined carbon content is between 0·80 per cent. and 1·00 per cent.; if the combined carbon content given above is exceeded a reduction in strength, which only terminates when the carbon is entirely in the form of carbide is witnessed. The following figures, given by Howe, are of value in this connection :—

As the tensile strength increases	From less than 20,000 lbs. per sq. in.	To more than 35,000 lbs. per sq. in.	Or by more than 15,000 lbs. per sq. in.
The total carbon content decreases	from 3·69 per cent.	to 2·98 per cent.	or by 0·71 per cent.
The graphite content decreases	from 3·12 „	to 2·22 „	or by 0·90 „
The combined carbon content increases	from 0·57 „	to 0·76 „	or by 0·19 „

The above table classifies the results of an examination of 180 samples of cast iron taken without selection.

According to Dr. Stead (British Foundrymen's Association Proceedings, 1915), an increase of each 0·1 per cent. of graphite may reduce transverse strength by 2 cwts. and tensile strength by 0·8 ton per square inch.

The fusibility of the iron carbon alloys increases as the total carbon content increases up to about 4·30 per cent.; beyond this point the melting points of the alloys are raised by additions of carbon. Other effects of increased total carbon are decreased tensile strength, increased machinability and decreased chilling power. The last phenomenon is occasioned by the difficulty of retaining carbon as carbide, which naturally increases as the amount of carbon to be thus retained increases. Given suitable means for preventing graphitisation, every increase in the content of total carbon leads to an increase in the hardness of the chilled surface of the alloy in question.

The machining of cast iron containing more than 0·80 per cent. of combined carbon is practically impossible.

3. The Influence of Silicon on Cast Iron.

Silicon varies from 0·20 to 4·00 per cent. in cast iron, but rarely exceeds 3·50 per cent. or falls below 0·50 per cent. It is present in cast iron, in all probability, as silicide of iron (FeSi), which is dissolved in the pure iron, or ferrite, of the alloy. The presence of this compound tends to strengthen and harden the ferrite. Silicon, however, has the effect of rendering cementite unstable, with the result that there is a tendency towards the formation of ferrite and graphite. Starting with white cast iron, the addition of silicon up to 1·00 per cent. results in an almost proportional decrease in the chilling power of the iron. Again, the addition of silicon to white cast iron leads to an increase in the strength of the resulting irons; this factor reaches a maximum when the content of combined carbon in the alloy is between 0·80 per cent. and 1·00 per cent. As the silicon percentage is further raised so are the combined carbon content and the strength of the cast iron lowered. When the silicon content is above 2·00 per cent. its hardening effect on ferrite is noticeable, iron relatively hard to machine being occasionally improved by a reduction of the silicon content.

The presence of silicon leads to a depression of the melting-point of cast iron; in similar manner the percentage of carbon in the eutectic alloy is reduced from 4·30 per cent. to 3·40 per cent. as the percentage of silicon increases up to 3·00.

Silicon has the effect of reducing the shrinkage of cast iron.

As a means of determining the correct proportions of carbon and silicon in cast iron, the following formula has, according to Mr. F. J. Cook, been used with marked success in practical working :—

$$X = \frac{O}{4{\cdot}26 \times \frac{Si}{3{\cdot}6}},$$

where

O = *total* carbon in percentage;
Si = silicon in percentage.

The elements carbon and silicon are in the best proportion when the value of X is as given below :—

For Ordinary work such as pans, grates, easily machined casting and pipes	X = 0·9 to 1
Locomotive cylinder (maximum transverse strength)	„ = 0·83
Steam, gas, Diesel and hydraulic cylinders (maximum tensile strength)	„ = 0·76 to 0·82
Chilled castings	„ = 0·75 to 0·8
Acid resisting	„ = 0·85

4. The Influence of Sulphur on Cast Iron.

Sulphur combines with iron to form a sulphide having a low melting-point, which occurs in steel in the form of ovoids, oval laminæ or membranes enveloping the ferrite grains. The presence of this sulphide is the cause of red shortness.

In cast iron this sulphide may modify the properties of the alloy owing to its manner of aggregation, but it is deleterious chiefly on account of its tendency to segregate and its powerful effect on shrinkage, which it increases. Sulphur tends to restrain graphitisation, hence it increases the chilling power of cast iron and may, therefore, be termed a hardening agent. This element should, however, be employed with great caution, if at all, in this capacity, on account of the objectionable properties previously stated. The presence of sulphur makes the molten metal thick and sluggish, giving rise to blowholes, yet this element in fair proportions, say 0·12 per cent., adds considerably to the wearing properties and strength of the metal. In every case, however, sulphurous iron *must* be cast as hot as possible if trouble is to be avoided.

Manganese and silicon are employed to counteract the evil effects of sulphur. Manganese reacts with iron sulphide, with resulting formation of manganese sulphide and liberation of iron. Under certain circumstances manganese sulphide is removable from cast iron, but even when retained its effects are not so deleterious as are those of iron sulphide. Silicon, owing to its strong tendency to induce graphitisation, resists the effect of sulphur in tending to retain carbon in the combined condition; it does not remove sulphur, nor does it prohibit the shrinkage due to sulphur or reduce the tendency towards cracking.

Sulphur is frequently limited by specification to 0·05 per cent., but in the hands of experienced and careful workers as much as 0·20 per cent. can be allowed without ensuing unsoundness. If the sulphur content of an iron is to be low the conditions under which it is prepared must be such that sulphur tends to be eliminated. Hence, coke low in sulphur must be used and suitable fluxes should be employed in the furnace for removing sulphur from the metal, e.g. lime, fluor spar or manganous oxide.

5. The Influence of Manganese on Cast Iron.

Manganese and iron unite to form a series of solid solutions whose freezing-point curve lies entirely between the freezing points of the component metals. The freezing points of all the alloys of pure iron and pure manganese are below that of pure iron. The freezing point of cast iron is depressed by the addition of manganese, not only on the above account but also owing to an increase in the degree of solubility of carbon in cast iron, which is brought about by the fact that the affinity of manganese for carbon is greater than that of iron for carbon. The depression of the freezing point reaches a maximum when the percentage of manganese is about 13.

The alloys of iron and manganese (pure) are harder than pure iron. Manganese therefore would, normally, have the effect of hardening the ferrite of cast iron were it not for the fact that its affinity, firstly for sulphur, and secondly for carbon, prohibits its solution in the ferrite.

Manganese, when added to cast iron, combines in the first place with such sulphur as is present in the iron; any excess above that required for the formation of manganese sulphide unites with iron carbide, with the formation of a double carbide of iron and manganese.

The quantity of manganese required to effect the entire conversion of the iron sulphide in the alloy into manganese sulphide is considerably more than that indicated by the equation—

$$FeS + Mn = MnS + Fe.$$

Manganese sulphide is characterised by the following physical properties:—

(1) High melting point—1400° C.;
(2) Insolubility in molten iron;
(3) Low specific gravity;

all of which assist in bringing about the separation of both manganese and sulphur from the molten alloy. Rapid cooling of the molten alloy leads to the more or less complete retention of manganese sulphide in the resulting solid alloy; slow cooling assists in separating the sulphide and bringing it into contact with the slag found on the surface of the alloy when the same is, for example, in the ladle. When the metal does not remain long enough in the ladle, or is not hot enough for the above to take place quickly, the manganese sulphide will be found on the top part of the casting in the form of hard spots, which are difficult to tool. Iron sulphide is deleterious in its action upon iron and steel. Manganese sulphide, though not beneficial, is of a somewhat neutral character. Manganese is, therefore, valuable as a desulphuriser.

Such manganese as is present in cast iron in excess of that required for the transformation of iron sulphide into manganese sulphide combines with the carbide of iron to form a double carbide, as stated above. Manganese is generally considered to induce the retention of the carbon in combination. This is true, but this effect does not make itself felt until the manganese content is well above that usually found in foundry irons. Hence, though hardness is increased by the addition of manganese, the cause is not usually the retention of carbon as carbide.

On the whole it may be said that, owing to (1) the tendency of manganese to produce brittleness and coarse crystallisation, and (2) its activity as a deoxidiser, it is inadvisable to add manganese to cast iron for the sole purpose of increasing hardness and chilling power.

Manganese increases the shrinkage of cast iron.

6. The Influence of Phosphorus on Cast Iron.

Phosphorus combines with iron to form a number of compounds, of which one, that containing three molecules of iron to each molecule of phosphorus, is of common occurrence in cast iron. The presence of phosphorus effects a reduction in the melting point of cast iron and a reduction in the total carbon content of cast iron.

As the phosphorus content of cast iron is increased up to about 0·40 per cent. so is the strength of the cast iron increased. Further additions of phosphorus appear to have but slight effect on the strength of cast iron until the percentage reaches about 0·75 per cent. Above this point the alloys are liable to be brittle, and unless fluidity is more important than strength 0·75 per cent. of phosphorus should not be exceeded. For thin castings in general, which are not required to be strong, the phosphorus can be increased to 1·5 per cent. or more, but in thin castings such as automobile cylinders, which are required to withstand wear and tear, not more than 0·30 per cent. of phosphorus should be allowed, owing to the slight tendency towards segregation of high phosphide irons.

7. Semi-Steel.

Semi-steel is simply cast iron made from a furnace charge of cast iron to which mild steel or wrought iron has been added. Additions of from 10 to 25 per cent. of steel are usual, but 30 and occasionally 40 per cent. are not unknown. As steel is low in carbon, silicon and phosphorus, the final cast iron (for it is still a true cast iron) is low in these elements. The steel should be added as sheared clippings or other small pieces, but not as borings, which take up too much sulphur. Iron appears not to take up sulphur from gases, but only by direct contact with the coke, hence the air furnace gives irons lower in sulphur than the cupola and is specially suited for melting steel with pig irons. Perfectly good results are, with care, obtainable from the cupola. There is, however, a tendency for the more fluid portions of a cupola burden of cast iron and steel to run first. Hence the first tap from the cupola is generally higher in carbon content than succeeding taps.

Tests for Cast Iron.

(Abstract of paper read by Mr. F. J. Cook before the Staffordshire Iron and Steel Institute, January 20, 1917.)

Important tests which are of use as a guide to foundrymen are :—

(1) Keep's shrinkage test;
(2) Transverse test;
(3) Hardness test;
(4) Casting temperature or fluidity test;
(5) Impact test.

(1) **Keep's Test** consists of casting ½ in. square bars between iron yokes, the ends of which are 12 ins. apart. When the bars have cooled down the shrinkage is shown by the difference between the length of the bars and the gap in the yoke in which they were cast; this is usually measured by inserting a taper graduated wedge in the gap and measuring off the dimension of the space.

This test is quite a comparative one, and when the amount of shrinkage which is associated with the most satisfactory castings has been arrived at, any deviation can be rectified by a little addition of silicon if the shrinkage becomes too high and *vice versa* when it is too low.

Under normal conditions a shrinkage of 0·183 in. = 1 per cent. silicon, and, to take the other extreme, 3·5 per cent. silicon is associated with 0·123 in. shrinkage.

(2) **Transverse Test.**—The following table gives average particulars of shrinkage, deflection and breaking load obtained with various classes of iron :—

Class of Material.	Shrinkage.	Deflection.	Breaking load.
	in.	in.	lbs.
Tough strong Iron	0·160	0·25	550
Hard " "	0·168	0·22	630
Soft Iron	0·123	0·18	423
Mottled Iron	0·207	0·11	375
White Iron	0·226	0·08	250

from which it will be seen that to obtain a big deflection strong irons are necessary.

(3) **Hardness.**—The most handy and reliable form of test is the 'drill test,' as all other methods deal with surface hardness only. The test may be made as follows :—Cast the metal into bars 1½ in. diameter, ½ in. being shaped off one side to give a flat surface to work upon, and

nove the outside skin. Drill four holes ¾ in. diameter, to a depth of 1 in., then the number of evolutions required to drill to this depth (the mean of the four holes being taken) indicates the general hardness. The angle of the drill should be ground exactly the same for each test, by neans of a suitable guide on the grinding machine. It is also essential to keep the same drill 'or the purpose, and preferably, two drills should be used and two holes drilled with each, which ninimises many discrepancies which otherwise might come in. The efficiency of drills is naterially affected by the sharpness of their point, and as cast iron is often not homogeneous and nay contain more or less hard spots a false result may be obtained owing to the point becoming nduly dulled by striking a hard spot in the early stages of the test. To avoid this a hole ½ in. liameter should be first drilled, which affords clearance for the point of the drill and ensures the ull cutting edge coming into operation. It is obviously necessary that the same weight be ttached to the drill and also that it runs at the same number of revolutions per minute for each est.

(4) **Casting Temperature.**—Low silicon cast iron is very prone to the effects of asting temperature, and some irons employed for such purpose are also liable to liquid con- raction. A handy workshop test for casting temperature with this class of iron consists in naking bars of the general dimensions shown in fig. 14. When cold the bars are broken through he line AB, the condition of the fracture giving an indication of the temperature at which

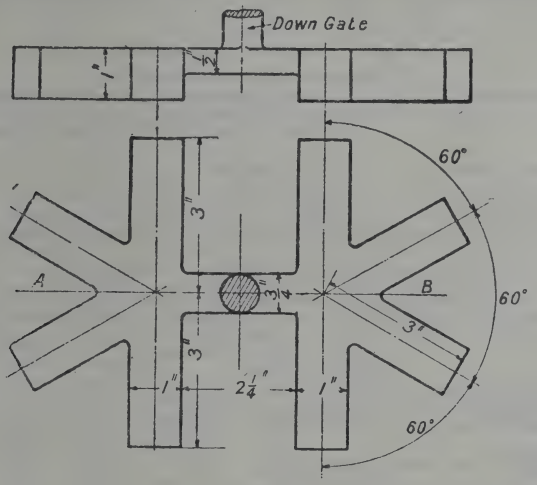

FIG 14.

ie metal was poured. Passing from the correct temperature (which is usually as hot as can be btained from the cupola) to very low, the following fractures will be observed—perfectly solid id homogeneous, then slight whitish centre, then brown centres of varying sizes and depth of lour as temperature is lowered and then black centre; with the latter is always associated open vities, and immediately above them is invariably found a gas hole.

For softer cast iron, which can be cast at a lower temperature without suffering the same fects as low silicon irons, a test bar in the form of a wedge is a very useful guide as to the uidity of the metal. Dimensions of such a test-bar used by the British Chuck and Piston ing Co. are length 9 ins., width 1 in., ⅜ in. thick at the largest end tapering to $\frac{3}{32}$ at the smaller, e bars being run from the thick end.

(5) **Impact Test.**—A satisfactory test is on bars 40 mm. square (1·57 in.) supported on ife edges 160 mm. (6·3 ins.) apart, and by dropping a weight of 12 kilos (26·5 lbs.) from a height 30 cm. (11·8 ins.) increasing the height of drop by increments of 5 cm. (1·9 in.) until such times the sample breaks, the height at which the bar eventually fractures being taken as the impact ure. Attached to the weight, in such a manner as to strike the bar parallel to the supporting ife edges, and the centre of same, is another knife edge. The face of all the knife edges should rounded $\frac{1}{16}$ in. radius.

A result of 55 cm. (21·5 ins.) is none too high for the work named, although this is quite a ere test. The maximum attained, as far as is known, has been 80 cm. (31·3 in.).

Span " "	1,000	1,000	1,000	1,000	1,000	1,000
E., lbs. sq. in., about	12,100,000	15,600,000	14,200,000	13,500,000	13,100,000	12,800,000

E—modulus of elasticity.

The above is taken from the practice of a large German engineering firm as published in the erman technical press in 1908. The test bars are round, of the varying diameters stated: all oss-breaking loads being on one metre (39·37 ins.) span.

STEEL.*

(Contributed by Ernest W. Birch, A.M.I.A.E.)

The term 'steel' is applied in a general sense to those alloys of iron and carbon whose carbon present entirely, or almost entirely, in the combined condition and whose total carbon content oes not exceed 2·00 per cent. In a special sense the term is applied to alloys of iron and carbon ith elements which are generally in excess of the carbon and whose presence considerably modifies e resulting alloys; such alloys are generally referred to as 'alloy or special steels.'

Steel is always contaminated by some or all of the elements—manganese, silicon, sulphur id phosphorus, and the allowable percentages are given in the following specifications. Sulphur id phosphorus should be kept as low as possible owing to the detrimental effect of these ements.

Carbon renders the steel susceptible to hardening, although below 0·2 per cent. steel ows no appreciable hardening effect when rapidly cooled. As the carbon percentage increases, does the tenacity and hardness, with a corresponding reduction in the ductility and toughness.

Steel is generally graded according to the percentage of carbon present. A general classifi-tion is as follows:

Carbon under 0·10 per cent.	Dead soft steel, very mild or extra mild steel, very low-carbon steel.
Carbon 0·10 to 0·25 per cent.	Mild steel, soft steel, low-carbon steel.
Carbon 0·25 to 0·60 per cent.	Medium-carbon steel, medium high-carbon steel, half-hard steel.
Carbon 0·60 to 1·20 per cent.	High-carbon steel, tool steel, hard steel.
Carbon over 1·20 per cent.	Extra-hard steel, very high-carbon steel.

The classification is not rigid, as no attempt has been made to standardise the various grades. further classification is made with carbon tool steels, the steels being graded according to their emper.' (This term has no connection with the term 'tempering,' used in thermal treatment.) he Temper numbers are arbitrarily chosen by the makers, and the following is an example:

Temper No.	Carbon Content.
	Per cent.
1	1½
2	1¼
3	1⅛
4	1
5	⅞
6	¾

* See also 'Tool Steel,' p. 1136.

The critical points in a straight carbon steel are dependent on the amount of carbon presen and these critical points control the temperature for forging, annealing, hardening, and temperin The higher the carbon content the lower the critical temperatures and the more sensitive is t steel. For the before-mentioned steels the recommended working temperatures are as follows:

Carbon Content. Per cent.	Forging Temp. ° C.	Annealing Temp. ° C.	Hardening Temp. ° C.
1⅓	800	720	760
1¼	825	720	760
1⅛	850	720	770
1	875	720	770
⅞	900	750	785
¾	950	770	800

The tempering temperature depends on requirements. The higher the reheating (temperin temperature, the greater is the loss in hardness, with a corresponding increase in the ductility (s pp. 1137 and 1144).

Carbon Content.	Suitable for:
Per cent.	
1⅓	Special turning and planing tools.
1¼	The most suitable for turning and planing tools, twist drills and small cutters.
1⅛	For large turning tools, circular cutters, taps, small punches, reamers, screwing dies, and small shear blades.
1	For hot setts, large punches, large taps, cold chisels, etc.
⅞	For chisels, setts, dies, smiths' tools, large shear blades, masons' tools, etc.
¾	For hammers, general dies, and miners' drills.

Having selected the correct quality steel for the particular purpose, it is essential to give t correct heat treatment in order to obtain the best results. The hardening temperatures a given in the previous table. The following table gives the necessary tempering temperature:

Tempering Temperature, ° C.	Suitable for:
300	Springs.
298	Wood saws.
295	Circular saws for metal.
290	Cold chisels for wrought iron.
285	Moulding and planing cutters for soft wood, needles, cold chisels for cast iron
280	Firmer chisels, saws for bone and ivory, cold chisels and setts for steel, gimlets.
275	Hot setts, axes, and adzes.
270	Augers, pressing cutters, flat drills for brass.
265	Coopers' tools, wood borers, twist drills, stone-cutting tools.
260	Plane irons, gouges, planing and moulding cutters.
255	Moulding and planing cutters for hard wood, punches and dies, cups, snaps, and shear blades.
250	Penknives, chasers, mill chisels and picks, taps, rock drills, screw-cutting dies.
245	Leather-cutting dies, boring cutters, reamers.
240	Bone-cutting tools, milling cutters, drills, wood engraving tools.
235	Paper cutters, planers for iron.
230	Ivory-cutting tools, planes for steel, screwing dies for brass, hammer faces.
225	Light turning tools, steel engraving tools.
220	Scrapers and lathe tools for brass.

CARBON AND ALLOY STEEL SPECIFICATIONS.

The following data are based upon B.E.S.A. Report 5005–1924 and upon the very complete specifications prepared by the S.A.E. (Society of Automotive Engineers, U.S.A.).

The range of steels given covers practically all general requirements. The selection of a given steel for a given part must depend upon an intimate knowledge of a number of important factors, such as the detailed design of the part and the severity of the service to be imposed, whether the part is to be machined or forged, machinability, and the method of manufacture. From the data given, a steel can be selected from a consideration of physical properties, after which the final choice depends upon such considerations as machinability, heat-treatment, etc.

Carbon Steels.

Reference No.	Carbon Range.	Manganese Range.	Phosphorus. Max.	Sulphur. Max.
1	0·05–0·15	0·30–0·60	0·045	0·05
2	0·10–0·20	0·30–0·60	0·045	0·05
3	0·15–0·25	0·30–0·60	0·045	0·05
4	0·20–0·30	0·50–0·80	0·045	0·05
5	0·25–0·35	0·50–0·80	0·045	0·05
6	0·30–0·40	0·50–0·80	0·045	0·05
7	0·35–0·45	0·50–0·80	0·045	0·05
8	0·40–0·50	0·50–0·80	0·045	0·05
9	0·45–0·55	0·50–0·80	0·045	0·05
10	0·90–1·05	0·25–0·50	0·045	0·05
11	0·45–0·55	0·90–1·20	0·045	0·05
12	0·55–0·70	0·90–1·20	0·045	0·05
13	0·08–0·16	0·60–0·80	0·09–0·13	0·075–0·15
14	0·15–0·25	0·60–0·90	0·06– max.	0·075–0·15

Steels Nos. 1 and 2.—Used for tubing and pressings; they are soft and ductile and will stand much deformation without cracking. Low tensile strength in annealed condition, but the yield point can be raised considerably by cold-working. They do not machine freely and will tear badly in turning, threading, or broaching. Machining properties can be improved by quenching in water from 925° C. Suitable for case-hardening.

Steel No. 3.—Forges well and machines better than No. 1 and 2. Can be used for machined forged, and case-hardened parts where no great strength is required. Can be drawn into tubes and cold rolled, and for cold-worked shapes that do not require deep drawing. When cold worked, yield point 18–35 tons per sq. in. in rounds not over $\frac{1}{2}$ in. diam. or in flats $\frac{1}{4}$ in. thick. Heat treatment will refine the grain after rolling or forging. Particularly suitable for case-hardening.

Steels Nos. 4 and 5.—Suitable for forged, machined, or cold-worked parts requiring higher physical properties than No. 2, also more responsive to heat-treatment and machines better. These steels should not be used for case-hardened parts.

Steels Nos. 6 and 7.—Medium carbon steels possessing good machining properties, and are suitable for small and medium-size forgings. After heat-treatment Brinell range 174–212.

Steels Nos. 8 and 9.—Medium carbon steels suitable for large forgings. Can also be used for a wide range of parts from bar stock. After heat-treatment Brinell range 192–235.

Steel No. 10.—Suitable for leaf springs and certain coiled springs. Heat-treatment: heat to 760–780° C., quench in oil, water, or brine, depending on size and shape of part. Draw to required hardness.

Steels Nos. 11 and 12.—Suitable for helical springs made of round cold drawn wire up to $\frac{5}{16}$ in. diam. No. 11 steel is recommended for wire from 0·025 to 0·100 in. diam., and steel No. 12 for wire 0·100 in. diam. and larger.

Steels Nos. 13 and 14.—Suitable for 'screw stock'; they machine very sweetly and take a good finish, but owing to cold-shortness they are not suitable for parts subject to shock.

STRAIGHT NICKEL STEELS.

Reference No.	Carbon Range.	Manganese Range.	Nickel Range.
15	0·10–0·20	0·30–0·60	0·40–0·60
16	0·10–0·20	0·30–0·60	1·25–1·75
17	0·10–0·20	0·30–0·60	3·25–3·75
18	0·15–0·25	0·50–0·80	3·25–3·75
19	0·25–0·35	0·50–0·80	3·00–3·50
20	0·30–0·40	0·50–0·80	3·00–3·50
21	0·35–0·45	0·50–0·80	3·00–3·50
22	0·40–0·50	0·50–0·80	3·00–3·50
23	0·45–0·55	0·50–0·80	3·00–3·50
24	0·17 max.	0·30–0·60	4·75–5·25

In all cases sulphur max.: 0·045; phosphorus max., 0·040; silicon, 0·15–0·40.

Steels Nos. 15, 16 and 17 are suitable for case-hardening.

Steel No. 18 not recommended for case-hardening except for massive parts, owing to the reduced ductility of the core due to the increased carbon content.

Steels Nos. 19 and 20 are suitable for parts requiring considerable strength and toughness. Not suitable for case-hardening.

Steels Nos. 21 and 22. As the carbon content is higher than for steels Nos. 19 and 20, higher tensile strength and greater hardness can be obtained after treatment, but with a loss in ductile properties.

Steel No. 23 is suitable for large gears, etc.

Steel No. 24 is used for case-hardened parts that require an exceptionally tough core. When it is necessary to machine parts made of this steel after carburising, the nickel content should be kept as near the lower limit as possible.

NICKEL CHROME STEELS.

Reference No.	Carbon Range.	Manganese Range.	Nickel Range.	Chromium Range.
25	0·10–0·20	0·30–0·60	1·00–1·50	0·45–0·75
26	0·20–0·30	0·50–0·80	1·00–1·50	0·45–0·75
27	0·35–0·45	0·30–0·60	1·50–2·00	0·90–1·25
28	0·17 max.	0·30–0·60	3·00–3·50	1·00–1·50
29	0·20–0·30	0·30–0·60	2·75–3·5	0·50–1·00
30	0·35–0·45	0·30–0·60	3·25–3·75	1·25–1·75
31	0·10–0·20	0·30–0·60	2·75–3·25	0·60–0·95
32	0·45–0·55	0·30–0·60	2·75–3·25	0·60–0·95

In all cases sulphur max.= 0·04; phosphorus max. = 0·04; silicon = 0·15–0·40.

In general these steels give higher tensile values and greater toughness than the corresponding straight nickel steels. They are, however, more sensitive to heat treatment.

Steel No. 25 is primarily intended for case-hardening, but can also be used for structural parts with suitable heat treatment. Where these steels are used for gears where considerable strength and a high degree of accuracy are called for, the gears should be normalised before carburising.

Steels Nos. 28 and 31 are suitable for case-hardening when a core possessing great strength and toughness is required.

The remaining steels are suitable for such heat-treated parts, either machined or forged, as require exceptionally high physical properties, and must be capable of resisting severe dynamic stresses in service.

MOLYBDENUM STEELS.

Reference No.	Carbon Range.	Manganese Range.	Chromium Range.	Nickel Range.	Molybdenum Range.
33	0·25–0·35	0·40–0·70	0·50–0·80	—	0·15–0·25
34	0·35–0·45	0·40–0·70	0·80–1·10	—	0·15–0·25
35	0·45–0·55	0·40–0·70	0·80–1·10	—	0·15–0·25
36	0·10–0·20	0·30–0·60	—	1·5–2·0	0·20–0·30

In all cases sulphur max. = 0·045; phosphorus max. = 0·040.

In general these steels have similar physical characteristics to the corresponding nickel and ckel-chrome steels. Steel No. 36 is suitable for case-hardening.

CHROMIUM STEELS.

Reference No.	Carbon Range.	Manganese Range	Chromium Range.	Sulphur Max.	Phosphorus Max.
37	0·15–0·25	0·30–0·60	0·60–0·90	0·045	0·04
38	0·35–0·45	0·50–0·80	0·80–1·10	0·045	0·04
39	0·45–0·55	0·50–0·80	0·80–1·10	0·045	0·04
40	0·95–1·10	0·20–0·50	1·20–1·50	0·030	0·03

Steel No. 37. This steel is primarily for case-hardening. For structural purposes the romium content of this steel gives a deeper penetration of the effect of heat treatment than n be obtained in a straight carbon steel having a similar carbon content.

Steel No. 39 is an oil-hardening type of steel intended for heat-treated forgings that require eater strength and toughness than are obtainable with straight carbon steels, or with some of e simple alloy steels having a lower carbon content. It also has a wider heat-treating range an the other simple alloy steels.

Steel No. 40 is used chiefly for the races and balls or rollers of anti-friction bearings. The romium and carbon contents cause a maximum penetration of the effect of heat treatment d give a high degree of hardness.

CHROME VANADIUM STEELS.

Reference No.	Carbon Range.	Manganese Range.	Chromium Range.	Vanadium.	
				Min.	Desired.
41	0·15–0·25	0·50–0·80	0·80–1·10	0·15	0·18
42	0·25–0·35	0·50–0·80	0·80–1·10	0·15	0·18
43	0·35–0·45	0·50–0·80	0·80–1·10	0·15	0·18
44	0·45–0·55	0·50–0·80	0·80–1·10	0·15	0·18
45	0·90–1·05	0·20–0·45	0·80–1·10	0·15	0·18

Steel No. 41 is intended primarily for case-hardening and can be used for structural parts er suitable heat treatment.

Steels Nos. 42 and 43. These steels can be used in place of the nickel and nickel-chrome els of similar carbon content for heat-treated forgings requiring greater strength, toughness l resistance to fatigue than it is possible to obtain with straight carbon steels.

Steel No. 45 can be used for anti-friction bearings and is used extensively for machine-tool ts, being primarily a tool steel.

SILICO MANGANESE STEELS.

Reference No.	Carbon Range.	Manganese Range.	Silicon Range.
46	0·45–0·55	0·60–0·90	1·80–2·20
47	0·55–0·65	0·60–0·90	1·80–2·20

Sulphur and phosphorus = 0·045 max.

These steels are essentially spring steels, but may be used for gears. In either case the ste must be suitably heat-treated.

HEAT TREATMENT.

In order to obtain the desired physical properties from steels it is generally necessary to sul ject them to a thermal treatment. The subject of heat treatment embraces the operations (*a*) normalising, (*b*) annealing, (*c*) hardening, (*d*) cementing, carburising or case-hardening, (*e*) t tempering or drawing of hardened steels.

The nomenclature and definitions relating to heat treatment as given by B.E.S.A. Repo No. 5005–1924 are as follows :

(*a*) **Normalising.** Normalising means heating a steel (however previously treated) to temperature exceeding its upper critical range, and allowing it to cool freely in air. It is desi able that the temperature of the steel shall be maintained for about 15 minutes, and shall n exceed the upper limit of the critical range by more than 50° Centrigrade.

(*b*) **Annealing.** Annealing means reheating followed by slow cooling. Its purposes may
(1) To remove internal stresses or to induce softness, in which case the maximum temper ture may be arbitrarily chosen.
(2) To refine the crystalline structure in addition to the above, in which case the te perature used must exceed the upper critical range as in normalising.

(*c*) **Hardening.** Hardening means heating a steel to its normalising temperature, a cooling more or less rapidly in a suitable medium, e.g. water, oil or air.

(*d*) **Cementing.** Cementing means heating a steel above its normalising temperature a medium which will increase its carbon content. The core of a case-hardened bar is the interi portion of the bar which is substantially unaffected by the cementing process.

(*e*) **Tempering.** Tempering means heating a steel (however previously hardened) to temperature below its carbon change-point with the object of reducing the hardness or increasi the toughness to a greater or less degree.

(*f*) **Refining** (cemented parts). Refining means reheating a steel to its normalisi temperature, and is usually followed by quenching.

See also p. 2745.

Effect of Tempering.

3½ per cent. nickel steel, oil-hardened at 860° C. and tempered at the temperatures indicate

Tempered at. ° C.	Yield Point. Tons per sq. in.	Ultimate Stress. Tons per sq. in.	Elongation. %.	Reduction of Area. %.	Impact. Test. Ft.-lbs.	Brinell No.
Not tempered	102·0	116·0	10·0	23·0	6	514
200	92·5	101·0	10·5	32·5	5	461
300	83·0	92·5	12·0	40·0	5	415
400	66·4	76·3	15·1	50·0	11	352
500	54·5	63·5	20·0	59·5	50	285
600	44·0	53·0	25·0	64·5	73	241
650	40·0	49·0	27·0	66·0	82	235

Effect of Mass.

The effect of mass must receive serious consideration when dealing with the physical pr perties of any heat-treated steel.

The hardening operation consists of heating the steel through and just above its critical ran in order to obtain the condition of solid solution, and quenching with sufficient rapidity to reta this condition. With large masses it is practically impossible to obtain a uniform temperatu throughout the mass on heating, the interior portion always being at a lower temperature th the outside. On quenching the heat is absorbed from the outside, and in many cases it is i possible, even with the most drastic quenching, to remove the heat sufficiently rapidly to reta the desired structure in the core. Again, with very thin sections, the rate of cooling may sufficiently rapid if carried out in air. Only by experience can the effect of mass be correct estimated.

The following table shows the effect of mass on the physical properties of a 5 per cent. nicke ase-hardening steel. Bars of varying diameters were given exactly the same treatment and hen tested :

Size of Bar. In.	Heat Treatment.	Yield Point. Tons per sq. in.	Ultimate Stress. Tons per sq. in.	Elongation. %.	Reduction of Area. %.	Impact. Test. Ft.-lbs.	Brinell No.
¼	Carburised at 860° C.	40·0	51·0	27·0	66·1	55	235
¾	Reheated to 860° C.	34·5	44·6	31·0	68·3	90	212

The figures given after water- or oil-quenching represent the hardened condition. Intermediate values, ranging from the values given for the normalised condition to the hardened condition, are obtained by tempering, as shown in the following table, which gives the values for a 3½ % nickel steel.

Invar.*

Invar is a nickel steel containing about 36 per cent. nickel, together with about 0·5 per cen each of carbon and manganese, with metallurgically negligible quantities of sulphur, phosphoru and other elements. It is made either in the open-hearth furnace or by the crucible metho It melts sharply at 1425° C. Above some 200° C. to its melting point, invar may be considere to consist of a homogeneous solid solution of iron, nickel and carbon. Below 200° C. and a a temperature dependent on its history and exact composition it undergoes a reversible trans formation of such a nature that for any sample the transformation may be incomplete. Thi condition of thermo-chemical instability gives rise to both slowly changing and quickly changin values of its physical properties—changes which are particularly manifested in the expansion.

Invar can be forged, rolled, turned, filed and drawn into wires, and it takes a beautiful polish giving an excellent surface on which fine lines may be ruled. In general it should be worke slowly. It will withstand without spotting the corrosive action of water. Its density is abou 8·0 grm. per cm.^{3}, its electrical resistivity is of the order of 80 microhm per cm., or about eigh times that of pure iron, and its temperature coefficient of electrical resistance about 0·001 per degree centigrade. It is ferromagnetic, but becomes paramagnetic in the neighbourhoo of 165° C.

The mean coefficient of linear expansion between 0 and 40° C. is in the order of one millionth for the ordinary invar, and samples have been prepared with even small negative coefficients the amounts of carbon and manganese present appear to exercise considerable influence on th expansion. Above 200° C. the expansion of invar is approximately that of Bessemer steel.

Invar is subject to changes in length due to 'after effects' following cooling from a high temperature, and to changes in length following even slight alterations in temperature. Inva also gradually elongates with time, forged and drawn material behaving somewhat differently i this respect, so that there is a determinable, seasonal correction to be applied to its length when used as a length standard. It also shows marked magnetostriction phenomena or changes o length accompanying changes in strong magnetic fields.

Mechanical properties: Tensile strength, 22·5–36 tons per sq. in.; elastic limit, 3·1–13·5 tons per sq. in.; elongation, 40–50 per cent.; reduction of area, 40–65 per cent.; Brinell hardness 160; scleroscope hardness, 19; modulus of elasticity, 22,500,000 lbs. per sq. in.

Expansion of Nickel Steels (Guillaume).

Mean coefficients of linear expansion between 0° and t° C. Applicable between 0° and 38° C.

36·4 + 0·9 Cr.	$4·433 - 0·00392\,t$

Cobaltron Steel Alloy (Patent).

This alloy (patent) introduced by Messrs. Darwin and Milner, of Sheffield, is made by adding cobalt to chromium-carbon steel. The maximum temperature necessary for the hardening is 1000° C. (tungsten steel requires from 1250° to 1350° for the best results) and hardening is said to be satisfactory when the steel is allowed to cool naturally in still air. Analysis of cobaltron shows that the following elements approximate to the amounts stated below:—

Carbon	About 1·5 per cent.	Molybdenum	About 1·25 per cent.
Cobalt	„ 2·25 „	Tungsten	„ 0·25 „
Chromium	„ 11·0 „		

* Extract from Circular No. 58, Bureau of Standards.

'Heenan' Oil Coolers for Heat Treatment of Steel.

The continuous introduction of hot steel into oil quenching tanks naturally heats up the oil, which retains heat for a long time, and rapidly becomes too hot to permit of the process being carried on.

Owing to the poor heat conductivity of oil, such arrangements as water-jacketing the tank or inserting pipe coils through which water is circulated are ineffective, the cool surfaces affecting only that portion of the oil in immediate contact therewith, while allowing the main body to remain over-heated.

The 'Heenan' system of oil cooling is to extract the hot oil by means of a suitable centrifugal pump, and pass it through a 'Heenan' oil cooler before returning it to the quenching tank. This oil cooler is built up on lines similar to those of the water cooler described on p. 1296. In effect, oil is spread over a large cooling surface with which cool air from the surrounding atmosphere is then drawn into contact. Circulating water is not used.

This machine has been applied amongst other purposes to quenching processes in connection with the hardening and tempering of gun tubes, rifle barrels, steel tools, gear wheels, springs, aeroplane engine parts, etc.

Chromium Plating of Steel.

Using solutions of 3 grams per litre chromium sulphate and 200-400 grams per litre chromic acid, good adherent deposits of chromium on iron can be obtained. The cathode current density range for good deposits should be from 100–150 amperes per sq. ft.

Best results are obtained using Sargent's solution of 3 grams per litre chromium sulphate, 245 grams per litre chromic acid, and a current density of 125 amperes per sq. ft., the anodes being of chromium.

Chromium-plated iron and steel have a hard, bright, silver-like surface, resist atmospheric corrosion indefinitely, and are resistant to the action of fumes of nitric acid, hydrogen sulphide, and ammonia. They also resist the corrosive action of molten tin, zinc, and brass. Steel does not lose its temper during chromium plating.

(See also p. 2708.) (*Chemical and Metallurgical Engineering, April* 21, 1924.)

CASE-HARDENING.

The case-hardening of steel is dependent upon the fact that above certain temperatures the affinity of iron for carbon is so great that when iron or steel is heated at these temperatures in contact with suitably chosen carbonaceous materials ready absorption of carbon supervenes. The quantity of carbon that can be absorbed by iron or steel under the above conditions varies according to the following factors—

1. The composition of the iron or steel.
2. The temperature at which the process is conducted.
3. The length of time during which the process is continued.
4. The nature of the carburising material.

The Composition of the Iron or Steel.

Case-hardening, in the accepted sense, is rarely practised on steel containing more than 0·20 per cent. of carbon or 0·40 per cent. of manganese. The process is stated by Guillet to be hindered by the presence of nickel, silicon and aluminium, and hastened in the presence of manganese, tungsten, chromium and molybdenum.

The Temperature at which the Process is Conducted.

The process is best conducted at temperatures above the critical range of the iron or steel treated. The usual temperatures for carburisation vary from 900° C. to 1000° C. The higher the temperature of carburisation the greater the rate of absorption of carbon and the deeper the effect of absorption.

The Length of Time during which the Process is Continued.

This factor can only be determined by experiment. It is generally considered that the best results are obtained when the carbon content of the surface layers of the case-hardened material are of eutectoid composition (about 0·90 per cent. C.).

The Nature of the Carburising Material.

The carburising material may be either solid, liquid, or gaseous. Solid materials are employed more generally than are liquid or gaseous materials.

Solid Case-hardening Materials.

For the purpose of obtaining deep 'cases' the articles to be hardened are packed in a suitably designed box with solid case-hardening substances or mixtures of substances, of which the following are examples :—

Charcoal (animal or wood).
Charred leather.
Crushed bone or horn.
Barium carbonate 40 per cent. and charcoal 60 per cent. (Caron's mixture)
Charcoal (wood) 95 per cent. and soda ash 5 per cent.
Charcoal (wood) 90 per cent. and common salt 10 per cent. (Guillet).

As case-hardening composition is bought by weight, and is required to fill up the case hardening boxes, the specific gravity is an important consideration. The speed of conduction of heat through various depths of carburising material requires determining by experiment. A good case-hardening material should not diminish in volume appreciably during the carburising operation, and should be free from sulphur and phosphorus.

The box should be of plate iron not less than $\frac{1}{8}$ to $\frac{1}{4}$ inch thick. The lid of the box has two holes pierced in it for drawing testing-pieces out if required. For small articles a piece of wrought iron tube, plugged or capped at one end, may be used; the other end is closed by a second plug fastened with an iron pin passing through it and the pipe, the whole being luted with fine clay. The articles being previously finished, except polishing, are put into the box in alternate layers with the carburising mixture, commencing at the bottom of the box with carburising mixture to the thickness of about $\frac{1}{2}$ inch; upon this a layer of the articles is placed, then another of carburising mixture about one-third the thickness of the first, and so on until the box is nearly full, finishing with carburising mixture about the thickness of the first layer, leaving room every way for the expansion of the articles by the heat, otherwise they will bend each other in the box. The packing completed, the lid is put on, the box luted and placed in a suitable furnace. The contents of the box require to be very gradually and uniformly heated to redness, and retained at this heat for the period required for the depth of caburisation desired. The depth of carburisation depends on the length of time the temperature is kept up. For testing pieces plain pieces of the same kind of iron as the articles may be used. They require to be brightened, and are placed, at the time of the packing of the box, in the central part, in such a manner that they may be readily pulled out through the holes in the lid, either by a piece of iron wire attached or by being made long enough to project through the holes, so that they may be gripped with pliers; the holes are luted the same as are the other parts. When the articles are sufficiently carburised the box is drawn from the fire, the lid taken off, and the contents are immersed in pure cold water: taken out when cold they are ready for polishing. To prevent rusting, the articles may be dried by riddling in a sieve with dry sawdust, after which they are wiped with a greasy cloth. If the articles be immersed in oil instead of water they will be much tougher but less hard, though sufficiently so for some purposes. It is not necessary to immerse them direct from the box, as it answers equally as well to allow them to remain in the box till cool, and then reheat them in an open fire and immerse them separately.

When the case-hardening is required to terminate at any particular part of the article, the part needed to be soft may be bound with iron wire and cased with loam. This prevents the iron from absorbing carbon at that part. The loam requires to be gradually dried on the article previous to putting in the box, otherwise it will crack. 'Harbee,' in a letter to *Engineering* (August 15, 1913), states that, in order to 'stop off' that portion of the article required to be kept soft, a thin coating of copper (one thousandth of an inch in thickness is sufficient) electrolytically deposited will effectually resist any attack of the case-hardening material. After case-hardening the film of copper can be readily removed by the aid of a pocket knife. Copper plating, however, is expensive. Another method is to cover the part needing protection with a copper tube (this is the most satisfactory method when the shape of the work will allow the use of the tube) or to paint it with a protecting paint (paint can be made from china clay and blacklead or from sodium silicate and sand). A frequent procedure is to carburise an object and allow it to cool in the box, finally machining off the carburised portion before quenching wherever it is desired to keep the surface soft. It is of course necessary to leave sufficient metal on the object before carburising in order to ensure complete removal of all carburised metal before quenching. With long objects, one end of which requires hardening while the other is to remain soft, it is possible to carburise the entire length, then reheat and quench one end only, allowing the other end to cool in air.

For the purpose of superficial case-hardening it is necessary only to heat the iron or steel to be treated to redness, to sprinkle one or other of the following finely powdered compounds or mixtures on the surfaces to be hardened, and to plunge the iron so treated into pure cold water. This method is simple and speedy, but the case obtained is insufficiently thick to resist much wear.

Potassium cyanide.

Potassium ferrocyanide.

Potassium ferrocyanide and potassium bichromate.

Sodium ferrocyanide 90 per cent. and anhydrous sodium carbonate 10 per cent.

Sodium ferrocyanide 80 per cent., anhydrous sodium carbonate 10 per cent., and potassium ferrocyanide 10 per cent.

Liquid Case-hardening Materials.

The immersion of steel articles in a bath of molten potassium cyanide (the fumes of which are of a highly poisonous nature) heated to 850° C. results in the formation of very hard but shallow cases.

Gaseous Case-hardening Materials.

The following gases have been employed for case-hardening iron and steel—illuminating gas, carbon monoxide, acetylene and petroleum vapour. All, according to Brearley, are supposed to be more effective if they are led through a solution containing ammonia, or otherwise are partly saturated with ammonia gas before entering the furnace. By increasing the pressure of the gaseous mixture it is possible to increase the rate of carburisation.

Rap d Case Hardening Methods.

One of the best is to instal a container for sodium cyanide and common salt mixed. These salts used molten are very efficacious, and many small parts can be thus cased without going to the trouble and expense of casing in boxes. The sodium cyanide needs careful handling, but it is a simple matter to arrange for it to be placed into the equivalent of a fume chamber, a place fitted with a fan so that an adequate draught will take away all the poisonous fumes.

The immersion of clean machined steel parts in the mixture will produce a reasonably deep case in the course of ½ to 1 hour, and there is the additional advantage that the parts emerge from the bath quite clean and bright and can be quenched for hardening at once. Some trouble may be experienced in obtaining a suitable container for these molten salts, but the use of one of the nickel-chromium alloys will give excellent results.

Another good method of obtaining a reasonable case on steel consists simply of playing an oxy-acetylene flame on the steel, and a very few minutes at a temperature of 900–1,000° C. will produce an adequate depth of case. The flame must be suitably regulated so that there is no danger of the steel being cut, but an excess of acetylene in the flame will prevent this and will cause the casing to be formed much more quickly.

These methods are those by which small parts may be quickly hardened on their surface and are not intended to supplant the ordinary box carburising.

(*'Machinery,'* May 12, 1927.)

Thermal Treatment of Case-hardened Materials.

Quenching.—If the quenching takes place directly after the carburising operation, the resulting product is liable to possess a coarse structure in both the core and the case. In order to improve the structure it is better to allow the work to cool in the box after cementation, and then reheat it in a separate operation. The reheat may be made bare in the furnace, but with large objects which take long periods to obtain the desired temperature it is advisable to protect them from decarburisation by covering them with charcoal or old case-hardening mixture. This second reheat is most satisfactory at temperatures of about 780° to 820° C. It is claimed that very good results may be obtained by reheating twice, first with a view to refining the core and secondly to refine the case. A sample treatment of this description is :—

1. Carburise at 900° C. and allow to cool in box.
2. Reheat at 900° C. bare, and allow to cool in air.
3. Reheat bare for 20 minutes at 810° C. and quench in water.

Another common treatment which is said to yield fine core structures is to reheat twice and quench after each reheat, e.g. :—

1. Carburise at 920° C.
2. Reheat to 900° C. and quench in oil.
3. Reheat to 810° C. and quench in water.

In order to refine the cores of case-hardened articles it is advisable to heat the same to at least 875° C. (unless the carbon content of the core is above 0·20 per cent.) and quench. This treatment refines the core of the article but coarsens the case, hence it is necessary to reheat to a temperature somewhat above the critical range corresponding to the carbon content of the case (775° C. to 825° C.), subsequently quenching the article in water, or in oil.

Quenching in water results in a much more rapid cooling than oil quenching; the former i necessary for ball races, cams, and all parts which have to be subjected to hard wear and requir extreme hardness (80 to 90 scleroscope). Oil quenching of correctly carburised mild stee results in a hardness of 50 to 70 scleroscope. Small objects cool more rapidly, and therefor become harder than large objects undergoing the same treatment.

Tempering of the quenched articles still further improves the properties of the same.

Annealing.

To Prevent Oxidation and Scaling during Annealing.

It is sometimes desirable that steel should be thoroughly annealed without any oxidatio and scaling whatever taking place. The most popular method of doing this is to simply pacl the stampings in sand, but this method is not good, because, unless the sand be extremely fine air will eventually percolate through the grains of the sand. The following method has bee found to give first-grade results, and steel articles may be heated for many hours and com out with a perfectly bright surface. The packing mixture consists of finely powdered burn lime containing a trace of powdered charcoal. A thick layer of lime is tightly rammed down i the bottom of a box, similar to those used for case-hardening purposes. The articles are place in position on the lime and a further layer of lime is tightly rammed down on top of them, wit a sprinkling of powdered charcoal on top of the lime. Several layers of articles may be packe in this way till the box is full, when it is covered with a lid and luted up with clay. Althoug this process is not so quickly performed as some, it gives excellent results.

If such articles as small die castings or brass or bronze extruded sections require to be annealed the articles are dipped in a saturated solution of borax or boric acid in methylated spirit. Th spirit evaporates at once, and leaves a sound protective coating of the solid which coagulate on heating and effectively resists the deleterious action of oxidising and other gases at tempera tures up to some 750 deg. C., which is as high a temperature as is usually employed for the genera heat-treatment of non-ferrous metals and alloys.

The coating of the borax or boric acid is so extremely thin that there is usually no necessit to remove it after heating, but should this be necessary, hot water will suffice.

(*Met., 'Machinery.'*)

For Welding and Cutting, see p. 2747.

CORROSION OF METALS.*

Corrosion of Iron.

Professor T. Turner in his book on 'Iron' says the results of the experiments of the Admiralt Committees which issued reports in 1877 and 1880 led to the conclusion that common iron wa less affected by corrosion than best Yorkshire iron, which is in accordance with the statemen of Gmelin that phosphorus diminishes corrosion in iron.

In these experiments :—

Common iron resisted corrosion better than Yorkshire iron 9·6 per cent.

Yorkshire iron resisted corrosion better than mild steel, 16 per cent.

In another series of experiments conducted by D. Phillips, in Cardigan Bay, and lasting fo seven years, it was found that the average corrosion of mild steel during the whole period wa 126 per cent. more than wrought iron.

The independent experiments conducted by T. Andrews also showed that wrought iron cor roded less rapidly than mild steel when the cleaned metallic surfaces were exposed to the actio of the water.

Iron rusts very quickly when immersed in water from bogs and marshes which contain a larg quantity of carbonic acid, derived from decayed vegetable matter.

Iron does not rust in dry air.

Iron subject to vibration rusts slowly. Railway rails in running roads where trains ar passing frequently rust much less than those in sidings which are little used. Rails which ar kept in reserve and not in use rust more quickly still.

Thin iron rusts more rapidly than thick, because the expansion and contraction owing t changes of temperature throws off the scales more quickly.

In moist air, steel rusts more rapidly than wrought iron, and wrought rusts more rapidly tha cast. (See table, p. 284.)

Cast iron in salt water becomes in time soft and porous. The smoother the surface of iro the more slowly it rusts.

Once rust forms the process goes on more rapidly; rust being a porous substance it absorb moisture and acids from the atmosphere.

* See also p. 284.

Protection of Iron from Rust.

The types of coating applied to iron and steel for their protection may be classified as follows :—

1. Adherent coatings. 2 Compound coatings.

1. Adherent Coatings.

These may be metallic or non-metallic in character. Of methods for the production of metallic coatings of this type the following are the most noteworthy examples :—

(*a*) *Galvanising.*—This is a process which has for its object the coating of the material with zinc. Two processes, known respectively as hot galvanising and electro-galvanising, are employed for attaining the desired object.

Hot galvanising consists in the immersion of the object to be protected from corrosion in molten zinc or spelter, the surface of which is largely protected from oxidation by a supernatant layer of ammonium chloride. Modifications of the simple process briefly described in the last sentence are known under the following names, Winiwarter's process, Kufler's process, Bedson's process, Reese's process, Porter's process, etc.

The amount of zinc on modern galvanised sheets varies from 1 to 2·5 oz. per square foot coated. The coating generally contains from 0·25 to 1·00 per cent. of lead and from 2 to 6 per cent. of iron.

The most obvious disadvantages of galvanising are two in number: first, the iron or steel coated has to be raised in temperature for the desired effect to be attained; second, a layer of weak zinc-iron alloy forms at some point intermediate between the true zinc layer and the iron or steel upon which it is designed to rest. This thin lamina of weak alloy, mainly the compound $FeZn_7$, may be insufficient in a majority of cases to cause trouble, but a serious reduction in tensile strength is frequently brought about as a result of the presence of this weak material in fine gauge wires and sheets.

Electro-galvanising (cold galvanising) consists in the deposition of zinc electrolytically upon the object to be protected from corrosion, a soluble zinc salt being employed as electrolyte. The most important process under this head is that of S. Cowper-Coles, wherein an electrolyte of zinc sulphate is used, the electrolyte being continuously regenerated by circulation through tanks containing zinc dust. The methods of cold galvanising associated with the names of Heathfield, Powick, Pottkoff, Rawson, Wagner, Walker, etc., are worthy of note. Particulars of their processes are obtainable in the technical press.

The electrolytic process leads to the formation of an intermediate lamina of only minute thickness. In this particular the coating produced by the electrolytic process is an improvement upon that obtaining as a result of hot galvanising. It is, however, porous, and in this respect is inferior to the zinc coating produced in the dipping process. No marked superiority can be claimed for either of the processes.

Electro-galvanising has made great progress during the past few years, and may now be regarded as an efficient method of rustproofing. By its means a wide range of articles may be coated with a film of zinc which, while ample to protect from oxidation, does not affect ductility or tensile strength. The fact that perfect cleanliness must be achieved before the adherence of zinc can take place prevents dirty patches on the article becoming coated. The main cause of failure with hot galvanised work is the covering up, through the surface tension of molten spelter, of dirty or scaly places, which blister or otherwise fail in a comparatively short time. A commercially protective coating is obtained with a deposit of 4 oz. per square yard of surface. The deposit is practically pure, lead being the chief adulterant, then only in a fraction per cent. Accurately machined parts can be assembled after coating, this overcoming a difficulty ever present in the past. Hot galvanised bolts must have the thread bared before the nut will fit. Cold galvanising coats the thread so that the configuration is not destroyed, and unless the nut is a very tight fit the zinc remains on the thread and thus protects it against corrosion.

Admiralty specifications require a deposit of 0·86 oz. of electro-deposited zinc per sq. foot of surface of the articles treated.

(*b*) *Tin plating* is a process similar to hot galvanising, tin being the coating metal. The protection afforded to iron and steel by tin is less effective than is that of zinc.

(*c*) *Terne plating* consists of the coating of the material to be protected with an alloy of lead containing from 50 to 75 per cent. of tin (generally 70 per cent. tin).

(*d*) *Lohmanising*—in this process the metals to be protected are (i) pickled in an acid bath, (ii) dipped into a salt bath which deposits a metallic salt over the entire surface of the body, (iii) immersed in a bath of molten alloy of zinc, lead and tin heated to a temperature of from 500 to 600° C. The composition of the tin-lead-zinc alloy is varied to suit the material being treated.

(*e*) *Electro-plating*—the coating of iron and steel electrolytically with copper, nickel, etc., is well known.

(*f*) *Copper* '*clothing*'—the casting of copper round or the welding of copper to steel a the rolling of the resultant material to the required shape and dimensions has been practised, e Monnot process, Willis process, etc. (vide *Iron Trade Review*, vol. li. 479).

(*g*) *Nickel* '*clothing*'—processes similar to the Monnot and Willis processes have been succes fully applied to the coating of iron and steel with nickel and cupro-nickel.

(*h*) *Metallic spraying*—the application of liquid metal in finely subdivided form by a sprayi machine has been accomplished by M. U. Schoop, whose process, 'the Schoop process,' allows the coating of iron or steel with an adherent layer of tin, lead or zinc, the material being coat remaining meanwhile at the ordinary temperature. The material under treatment must scrupulously clean if adhesion of the finely-divided spray is to be perfected (vide *Me Industry*, vol. xvi. 41).

Of methods for the production of non-metallic coatings of this type the following are the mo noteworthy examples :—

(*a*) *Painting* (see page 2788)—The term 'paint' is applied to such substances as a employed as protective coatings in liquid form, but which under the action of oxygen dry a finally become hard and resistant. Paints are composed of :—

(*i*) solid substance in a state of fine division (pigment);
(*ii*) liquid in which the solid is held in suspension (vehicle); and, frequently,
(*iii*) salts of manganese, etc., for the purpose of hastening oxidation of the vehicle (drie

Friend (*Carnegie Schol. Mem.* vol. ix. 1918, 117) summarises the conclusions respecting paint ironwork exposed to atmospheric corrosion as follows :—

1. The practical value of acceleration tests is shown to be very small in the present state our knowledge. Reliable results can only be obtained from tests carried out under conditio closely resembling those required in practice.

2. Addition of pigment to oil increases the efficiency of the latter as a protective paint un a maximum is reached. After this, further addition of pigment causes deterioration. The be results are obtainable from paints possessing as high a percentage of good oil as is compatible wi good body and any other working property that has to be considered.

3. Linseed oil on setting expands by some 3·3 per cent.: this is the primary cause of crinklin Further oxidation causes a decrease in volume; this in time leads to cracking.

4. Linoxyn is permeable to moisture. The permeability is reduced by heating in absence air, the oil increasing in density, viscosity, and molecular weight.

5. Polymerised linseed oil affords a better protection than raw oil when used as a paint vehici

6. The functions of a pigment are to toughen the film and render it less permeable to wat vapour and oxygen. It also reduces the expansion of the oil on setting and thus minimises t tendency to crinkle.

7. A thick coat of paint protects the underlying metal more efficiently than a thin coa provided the coat is not so thick that running or crinkling takes place.

8. The very best results are obtained by multiple coats. Two thin coats are better than o thick one of equal weight.

9. Thinners enable thin coats of paint to be applied. Turpentine leaves a very slight residu behind upon evaporation, but its effect on the efficiency of the paint is small.

10. Other things being equal, the most permanent paints are those containing black or re pigments, since these absorb the shorter rays of light and prevent them from hastening th destructive oxidation of the linoxyn by the air.

11. Finer pigments afford more efficient protection than coarse pigments, since they are mo thoroughly in contact with the oil.

12. Iron structures should be painted whilst their scale is still on after loosely adherent flake and rust have been scraped off. The paint will last rather longer than if applied to the pickle or sand-blasted surface, and the labour of removing the scale is saved.

13. Experiments with rusty plates are not conclusive, but suggest that the rust need not b so carefully removed, prior to painting, as is usually thought to be necessary.

(*b*) Varnishing—the term 'varnish' is applied to such liquids as are produced by the solutio of gums, resins, etc., in volatile substances such as spirit, turpentine, fusel oil, etc. Varnishes ar open to the objection that they are not entirely impervious to gases and liquids. The applicatio of several coats of varnish and the stoving of such articles as have been varnished tend to increas the efficiency of these types of protective. The former method of treatment is, of course, costly the latter can only be employed where relatively small articles are being dealt with.

Frequently mineral oxides, etc., are added to give 'body' to varnishes, and such protectives re far preferable to the mere gum or resin solutions mentioned above. Provided the solvent tilised in manufacture is not too volatile and the substances employed to give 'body' to the arnish do not act injuriously upon either the iron or the solute, these varnishes are of considerable alue. Of materials employed to give 'body' to varnishes, calcined hematite ores and the mixture f finely-divided zinc and zinc oxide ('blue powder') obtained in the distillation of zinc, are the ıost effective. (*Lewes.*)

(*c*) Coating with bituminous substances—the substances tar, pitch and asphalt, together ·ith other tar products of like nature, form excellent protective coatings for iron and steel. Care ·quires to be taken to ensure the absence of acid or alkaline substances from these bituminous ıaterials. Where the articles to be coated can be heated without deleterious effect most excellent enamels' can be produced by applying warm tar to the same as hot. A variety of coatings may e obtained by altering the relative temperatures of the articles to be treated and the bituminous ıaterial employed in treatment (*cf.* Angus Smith's process, page 2794).

(*d*) Coating with Portland cement—the use of cements as a protective coating is frequent ·here the same can be afforded suitable support. In many cases the difficulty of attachment f the protective coating more than counterbalances the rigidity and adherent properties of the ement. Consideration must, of course, be taken of the possible effect of metallic expansion and ontraction upon the cement coating applied, and cement should only be utilised where it can be pplied in relatively thick coatings and where one can be assured that rupture of the hardened ement will be unlikely.

(*e*) *Enamelling.*—The enamelling of iron and steel is frequently conducted with a view to fford protection to the same. The enamels employed are boro-silicates of sodium, potassium, ılcium, and aluminium. Finely-divided glass, flint or quartz forms the general source of the lica; felspar or clay that of the alumina. To render enamels translucent fluorspar is added, ·hile borax furnishes the anhydride of boron required to complete the true enamel. Soda ash nd pearl ash are utilised as fluxes. As oxidising agents the nitrates of sodium and potassium nd manganese dioxide are used in light- and dark-coloured enamels respectively. To give dhesiveness to such enamels as come into direct contact with the metals to be coated, oxide of obalt is employed. The following oxides are used as colouring agents:—

White, oxide of tin; blue, oxide of cobalt; violet, oxide of manganese; brown, oxide of ıanganese; grey, oxide of nickel; green, oxides of copper or of chromium; yellow, oxides f uranium or of titanium; red, oxides of iron, selenium, or of gold.

The enamel is put on either as a powder or as a suspension. It may be applied in one coat ther by dipping, by spraying, or by powdering. Sometimes, however, a non-vitreous base ıaterial is applied and burned in to make it adherent, after which the true enamel is introduced) the surface to be coated. In any case the finely-divided particles which form the basis of the namel are fused together in a solid coating of boro-silicate by subjecting the same to a tempera- ure of about 1,000°C. The process generally requires from 3 to 4 minutes.

A process similar in some respects to that of enamelling is Ward's inoxidising process, which onsists of the application of a solution of a silicate to the iron or steel to be protected. The articles) prepared are heated to such a temperature as will cause partial fusion of the silicate to occur nd union of the same with the iron finally to ensue (*cf.* also Dode's inoxidising process).

It is obvious from the above that enamelling can be applied to relatively few articles of impor- ance to the engineer.

2. Compound Coatings.

The term 'compound' is applied here to such protective coatings as are produced by chemical ction, the ultimate result of which is the formation of a chemical compound, such, for example, s magnetic oxide of iron (Fe_3O_4), iron-zinc ($FeZn_3$), etc. The compounds formed may be, as lready noted, either chemical (in the general sense of the term) or intermetallic (in the specialised ense of the term).

Chemical Compounds.

Barff's process consists in passing superheated steam over the objects, which are heated in an ir-tight retort to about 260° C.; for the formation of a more perfect protective coating higher emperatures are necessary (650° C.). Articles so treated are said to be 'barffed.' Relatively mall objects only can be treated as above. The coating formed consists of the mixed oxides of ron (Fe_2O_3 and Fe_3O_4).

The *Bower-Barff* process is an improvement on the above, and consists in the heating of the bjects to be protected to about 900° C., at the attainment of which temperature superheated team is introduced to the same, which has the effect of producing a coating of the mixed oxide lready referred to. This operation having continued for about twenty minutes, carbon monoxide s injected into the retort for a period of from fifteen to twenty-five minutes, during which time he entire reduction of the coating to the condition of magnetic oxide of iron is completed.

The *Gesner process* treats iron and steel at a moderately high temperature (550° C. to 650° C in a retort whereinto may be introduced an atmosphere of steam. The preliminary heatin occupies twenty minutes; the steam is then allowed to react with the oxide formed in the fir operation for about half an hour, when naphtha is introduced and allowed to remain in conta with the material under treatment for about ten minutes. Finally, steam is again introduce The whole sequence of operations occupies about one hour and twenty minutes.

The *Parker 'dry' process.*—Under a patent assigned to the Parker Rust-proof Company, Detroit, the formation of an adherent coating of oxide may be obtained by first heating the objec to be treated to about 600° F. and then subjecting them to fumes of the acid metaphosphates strontium, molybdenum and tungsten.

The *Hans Renold process.*—Remove all grease or oil from the articles to be treated b suspending in a bath of hot lyco (11 oz. per gal.) for about three minutes, wash in cold runnin water for a few seconds, then suspend from cathode brass bars by steel hooks in an electrolyt bath (KCN, 98 per cent. pure, 4 oz. per gal. of water), iron plates forming the anodes. Leav here for five minutes, and when a current of 25 amps. at 8–10 volts is passed through the bat all foreign matter on the surface will be removed. Wash off the cyanide by means of hot water t facilitate drying.

Heat the articles to 700° C., then quench in cotton-seed oil by immersing in the main body the quenching tank for seven or eight seconds before allowing to fall to the bottom.

Dry by heated sawdust and hot-air blast (dried and filtered by passing through calciu chloride and cotton wool).

Insufficient oxidation results in the finished bodies having a grey appearance, due to th atmosphere of the furnace containing too much gas. Blistering is due to overheating.

Villon's process consists in subjecting the iron or steel to be protected to the vapour of sulphu as a result of which treatment the monosulphide of iron is found.

The *Bertand process* requires that the articles to be treated be thoroughly cleaned by sand blasting or similar means before they are immersed in a bath, such as will lead to the depositio of copper upon the same as a result of reaction between the iron and a suitable electrolyte. Th deposition may be achieved by the application of electricity or by more purely chemical mean After thorough washing the articles are heated in an oxidising atmosphere to a temperature about 600° C., which treatment leads to the formation of a fairly adherent coating of magneti oxide of iron.

The *De Meietin's process* depends upon the formation of a coating of magnetic oxide (Fe_3O_4) upon iron or steel which is placed as the positive pole in a bath of distilled water, maintaine at a temperature of from 70° C. to 80° C., a current of electricity being passed through it. Th oxide coating is adherent, provided the current density is not over great, and may be rubbed an polished. This method is of value in the treatment of such articles as cannot be submitted t any processes which might tend to temper or anneal the objects under treatment.

The *Parker 'wet' process* (patent) consists in the immersion of the iron or steel to be protecte in a bath of a 1½ per cent. solution of the acid metaphosphates of tungsten, molybdenum, or an of the metals of the third, fourth or fifth group of elements.

The *Coslett process* (*Coslettising*).—Cast iron or steel articles treated by this process are no only rendered rust-proof but improved in appearance.

The articles to be treated should be perfectly clean and free from tin, nickel, or grease.

The best results are obtained on a frosted surface, such as is left by sand-blasting or pickling Sand-blasting is to be preferred, as any traces of acid render the treatment ineffectual.

The coslettising bath is prepared by heating in a cast-iron or welded steel tank a sufficien quantity of distilled water to easily cover the articles to be treated. When boiling add fo every gallon of water in the bath (1) two ounces of phosphoric acid (syrupy sp. gr. 1·5); (2) on ounce of iron filings. This should be carried out in the open or under an uptake, as the reaction results in the formation of disagreeable fumes. When this reaction has ceased the bath is ready for use.

The articles should be placed in the bath as soon as possible after sand-blasting, and should be gently boiled for two hours.

A second tank should be prepared containing distilled water, which should be heated in time to wash the articles as taken from the coslettising bath.

At the expiration of the specified time the articles should be taken from the coslettising bath nd placed directly into the hot water and thoroughly scrubbed with a stiff bristle brush.

They may then be dried off, and if heavy will dry quickly themselves, but if light should be laced in an externally heated oven.

As soon as dry and while warm they should be dipped in a mixture of lubricating oil and irps substitute, in the proportion of 2 to 1, and left to drain. When cold, surplus oil may be moved with clean waste or wiper.

To allow for evaporation of bath a mixture similar to that in the bath should be made up nd added as required.

To keep the bath at the correct strength it is necessary to titrate a sample of the bath with normal sodium hydrate. To make this test, 10 c.c. of the bath should be placed in a nical flask, a few drops of phenolphthalein solution being introduced as an indicator. The $\frac{1}{10}$ rmal sodium hydrate should be added from a burette, until a permanent pink tinge is given to quid in the flask. The amount of sodium hydrate dropped into the flask should be noted, and if e bath is correct this amount will be 10 c.c. If more sodium hydrate is used, the bath is too rong and will require diluting with distilled water; if less is used, the bath is weak and will quire the addition of phosphoric acid and iron filings in the given proportion.

The appearance of the deposit obtained on the article is a rough guide to the state of the bath. he proper deposit is of a uniform dull black colour, but if the bath is too strong this black coat covered with a pearly white deposit which will not scrub off. If the bath is too weak e articles appear unevenly covered with a thin grey coat.

It is stated that in the present coslettising process (which cannot be used except under licence om the Coslett Anti-Rust Syndicate) phosphorised zinc, made under special conditions, is used stead of phosphorised iron, the solution otherwise being prepared in much the same manner. his newer process is said to give much better results, and the depth to which the articles are st-proofed to be considerably greater.

The need for the absolute cleanliness of the articles before treatment cannot be too strongly mphasised, and they should not be handled after cleaning, or before they are finally oiled.

Intermetallic Compounds.

Sherardising.—The articles to be coated are first cleaned and dipped in an acid bath as for lvanising; they are then put in a suitable retort which is, if possible, airtight, and are rrounded with 'blue powder'; the retort is then raised to a temperature of 500° or 600° F.

If the retort cannot be made airtight, about 3 per cent. of finely powdered carbon should be ixed with the zinc to prevent the formation of zinc oxide.

The heat is kept up for a few hours, after which it is allowed to gradually decrease.

A coating is formed which consists mainly of an intermetallic compound of zinc and iron $FeZn_3$).

Calorising.—A somewhat similar process to the above, in which aluminium powder is utilised the agent and wherein the resultant protective coating consists chiefly of an intermetallic mpound of iron and aluminium.

RUSTLESS IRON.

The composition of rustless iron (carbon, 0·7; silicon, 0·8; manganese, 0·12; chrome, 11·7, d nickel, 0·57) is, except for a variation in the carbon content, the same as that of the steel ssessing similar qualities.

Stainless Steel.

Stainless steel or rustless iron are not altogether stainless or rustless under all conditions. oreover, the 'rustless iron' is really a dead-mild steel containing a certain percentage of romium, which gives the steel its corrosion resisting properties. Mild stainless steel contains out 11 to 14 per cent. chromium, with 0·1 per cent. carbon and under, the other constituents, icon, sulphur, phosphorus, and manganese, being all more or less in normal percentages. pparently when the cast contains 0·1 per cent. and less of carbon it is called 'rustless iron,' d above that percentage 'rustless steel.')

One of the valuable properties of mild stainless steel is its behaviour at high temperatures When pieces of the material which have been polished are heated up gradually, temper colour appear on the surface similar to those obtained when ordinary carbon steels are heated up, bu in the case of mild stainless steel these temper colours appear at much higher temperatures, a shown by the following table:

Colour.	Mild Stainless Steel.	Ordinary Steel.
	° C.	° C.
Pale straw	290	225
Straw	340	235
Brown purple	390	265
Purple	450	280
Bright blue	530	290
Dark blue	600	315

Up to temperatures of about 825° C., mild stainless steel resists scaling to a remarkabl degree, but above this temperature the material begins to scale to some extent.

Hot Rolling and Forging of Mild Stainless Steel.

The most suitable hot rolling temperature for this material is 1050° C. to 1100° C., and it i essential that for rolling and forging the material should be brought up slowly to about 900° C and then slightly quicker to the rolling and forging temperature. It should be allowed to soa for a long period to ensure a uniform temperature through and through.

For forging, it should be worked quickly and with rapid blows between the temperature of 1150° C. and 900° C. Below 900° C. to 850° C. it is not so easily deformed, and if any heav work is put on the material after it has fallen below these temperatures it is very apt to b badly stressed or burst.

For drop stamping, it is advisable to work at a slightly higher temperature, and all stamping must be trimmed while hot, or annealed before trimming on account of the air hardenin properties of the steel. Otherwise, if an attempt to trim is made, cracking and splitting wil occur, as well as damage to tools.

Annealing.

The critical range of mild stainless steel runs from about 865° C. to 965° C.

To anneal mild stainless steel to obtain the maximum softness, it should be heated up slowl to about 1000° C. and held at this temperature for a period of time in proportion to the mass o metal, and then allowed to cool off slowly in the furnace, making sure that no currents of col air enter the furnace.

Although steel annealed this way has the maximum degree of softness, it is not in the bes condition for machining. The steel in this state is very soft and tough, and so drags and tear when machined, leaving a very rough surface.

To soften the material for good machining properties or cold drawing and cold rolling, i is best to anneal at 750° C. to 800° C., preferably about 780° C., and then to cool in the furnac or draw and cool in the open air.

Mild stainless steel has distinct air hardening properties, so that it should always be annealed or high temperature drawn at 750° C. to 800° C. as stated above, after it has cooled down fro a hot rolling or forging temperature, before it can be successfully machined or cold worked.

Cold Rolling and Drawing.

The material will cold roll, cold draw and deep draw, or press very well, but owing to th percentage of chromium in the metal, the depth of each draw, when the steel is being deep presse or drawn, obtained at each operation is only about half that got when working on mild steel before the material must be annealed.

In cold rolling and cold drawing, the reduction of one gauge at a pass can be used, but it i found necessary to anneal after every second or third pass.

As with all materials, a distorted surface is always more liable to rust, and the same applie to mild stainless steel, especially if the surface happens to be unevenly distorted.

In cold working, strains are always set up in the material, and sometimes strained parts ar not confined to the surface where they can be ground off, but are inherent in the steel and th strains must be removed by heat treatment. These strains are not only liable to cause rust but are apt to cause the steel to crack if put into service. It is thus evident that it is advisabl to anneal or high temperature draw at 780° C. all material which has been cold worked in any way

Pickling.

The proper pickling of mild stainless steel is a very important factor in the manufacture of ticles of this material. If the steel is left coated with scale, or has small pieces of scale left the surface it will rust wherever the scale is present. It is therefore essential that the finished rface should be free from all scale, roakes, seams, pits, or cracks, or even stamp marks, as herwise rusting will result.

The acid pickling baths generally used for this material are as follows :

1. 50 per cent. solution of hydrochloric acid used hot at 60° C. to 70° C.
2. 15 per cent. solution of sulphuric acid used hot at 60° C. to 70° C.
3. Ten minutes in a 50 per cent. commercial hydrochloric acid, then transfer without washing to 20 per cent. nitric acid for 25 minutes, both these solutions being worked cold.

Of these acid pickling solutions, No. 3 is the one which has given the most satisfactory results. ther methods which have been used for cleaning this steel are electrolytic pickling in an alkaline ath, which has been more or less successful for bars, etc., and articles of simple shape. Acid ckles containing chemical salts to accelerate the action, have also been used with considerable ocess.

Grinding.

The grinding of mild stainless steel must be carried out very carefully, as this material is more fficult to grind than ordinary steel. This metal dissipates heat very slowly, and great care ould be taken in grinding in order that grinders' ' scorch ' is not produced. Grinders' ' scorch ' due to harsh grinding and produces a brownish discoloration on the steel. This discoloration really a temper colour produced by the heat generated on the surface of the work, and will use rusting, due to the local distortion set up. Wet grinding is much better than dry grinding.

Etching.

In etching mild stainless steel, the following solutions have given very good results :

1. A saturated solution of ferric chloride in hydrochloric acid to which a little nitric acid has been added. This solution is used full strength.
2. A mixture of hydrochloric acid and nitric acid in the proportion of three to one and used full strength after allowing to stand for about 24 hours.
3. A saturated solution of copper sulphate in hydrochloric acid. This solution is used for light etching.

Physical Properties.

The physical properties obtained from mild stainless steel in the annealed condition, and so in the hardened and tempered state, cover a very wide range ; this will be seen from the llowing table :

TABLE OF TESTS OF TEMPERED BARS.

Tempered at.	Yield Point. Tons per sq. in.	Tensile Strength. Tons per sq. in.	Elongation. Per Cent.	Reduction of Area. Per Cent.	Izod Impact. Ft. lbs.	Brinell Hardness. Kg. per sq. mm.
° C.						
200	66·5	73·0	12·0	37·5	35	340
300	66·0	72·5	12·5	37·0	39	332
400	65·5	72·3	16·0	50·0	38	332
500	59·0	72·5	18·0	52·0	36	340
600	38·0	48·0	22·5	62·0	66	235
700	31·0	41·0	27·0	66·0	80	192
750	28·0	36·6	30·0	69·0	88	174

These tests were made on ' as rolled ' and ' annealed ' bars quenched from 950° C. in oil and mpered at various temperatures.

Welding.

Mild stainless steel can be welded by either the electrical process or by the oxy-acetylene ethod. It will not weld by the usual method of heating in a smiths' fire.

In welding, the temperature of the metal at the weld is raised to a fairly high temperature, that the material on cooling down will air harden and should be annealed before any turning, inding, or polishing is done.

(H. S. Primrose, A.I.Mech.E., M.Inst. Met., Paper read before the Manchester Association of Engineers, Friday, December 19, 1924.)

Colouring Metals Electrolytically.

Chiefly in grey, so as to give the effect of old metal, is largely carried out.

When the colouring is only to be partial, a shellac or asphalt varnish is applied to the parts i is desired to leave untouched. The *Ironmonger* points out that with cyanide baths the retentio of the varnish on the metal is almost impossible, and that in all such cases it is desirable to us a bath of acid reaction.

For a grey surface on iron a bath of the following composition is recommended :—

12 litres water.		100 grammes	white arsenic.
4 „	crude hydrochloric.	100 „	green vitriol.

1 litre of ferrous chloride solution.

As usual with acid baths, a considerable strength of current is required. Plates of carbon ar used as anodes.

The bath can be used for colouring silver, nickel, German silver, etc., and by altering th composition of the bath and the current from grey to a deep black is produced ; but the blac adheres very indifferently—a high current is necessary for the latter. (*Horobin.*)

Electro-Deposition of Iron.

A bath that will give very satisfactory results is composed of 75 grms. of ferrous ammoniun sulphate to 1 litre of water, with a current density of 1 amp. per 30 sq. cms. To ensure a uniform deposit the anode should be moved about the work by means of a small motor. A good anod is made up of 16 S.W.G. Swedish iron wire wound into the form of a cylinder and thoroughl annealed. The temperature of the solution should be kept above 63° F., and it is desirabl to decant and settle it every three days or so to remove oxides of foreign matter which caus roughness in the deposited metal.

It has been found possible to coat with a layer 2 mm. thick any cylindrical wrought iron o steel surface. Properly done this layer cannot be chipped off with a chisel, and when carbonise and hardened the dividing line, shown by microphotographs, entirely disappears. The surfac can be filed or ground and given a high finish.

(*B. H. Thomas, 'Institution of Automobile Engineers.'*)

COPPER.

Copper containing at least 99·95 per cent. of the pure element is produced on a commercia scale in large quantities. The average tenacity of cast copper is about 10 tons per square inch, tha of worked copper is about 15 tons per square inch, while Roberts-Austen quotes the following figure for the mechanical properties of slowly annealed, hammered, rolled bars of copper of a high degre of purity :—

Elastic limit	1·16 tons per sq. in.
Maximum stress	13·47 „
Elongation	37·0 per cent.
Reduction of area	61·0 „

Impurities in Commercial Copper.

Arsenic.

Arsenic increases the hardness and the tenacity of copper. When present in moderate quantities it increases the percentage elongation of the metal. It improves the rigidity and strength of copper at high temperatures, hence, for fire-box plates, the use of copper containing from 0·3 per cent. to 0·5 per cent. of arsenic is frequently specified. In copper that is to be employed in the manufacture of brass subsequently to be cold-worked, not more than 0·05 per cent. of arsenic should be allowed.

Antimony.

Antimony is similar in action to arsenic, but it should be limited to traces in such copper as is to be used for the manufacture of brass that is to be cold-worked.

Bismuth.

Bismuth being the most deleterious element that can be present in copper, owing to its tendency to induce red-shortness, not more than traces of this element should be allowed.

Iron.

Iron is rarely present in copper in more than traces.

Lead.

Lead is, after bismuth, the most objectionable impurity likely to be present in copper, although it is of value in metal that is to be rolled into sheets, on account of its softening effect on copper. Not more than the smallest quantities of this element should be allowed in copper for cold-worked brass.

Nickel.

Nickel hardens copper, but is in no way deleterious when present in such amounts as are usual
commercial copper.

Oxygen.

Oxygen in small quantity does not have any very radical effect on the mechanical properties
copper. It is important in bringing copper up to the 'pitch,' and in combining with deleterious
purities to form insoluble and infusible compounds, thus separating and distributing these
purities and rendering them harmless.

Sulphur.

Sulphur tends to embrittle copper, but is rarely present in refined copper.

Tellurium.

Tellurium is similar to sulphur in its action on copper.

Silver, Tin, and Zinc.

Silver, tin, and zinc are sometimes present in copper, but are rarely present in such quantity as
have much effect on the metal.

It has been found practically impossible to cast copper which is mechanically sound and of
gh electrical conductivity, on account of the porous metal that is obtained. By an addition of
ron this can be accomplished. One per cent. of boron suboxide flux—equivalent to 0·08 to
1 per cent. of boron suboxide—is added to the copper, and a casting that is commercially sound
obtained.

ZINC.

Zinc is marketed in two forms—as sheet zinc (see Sheet Zinc Trade Gauge, page 2817) and as
elter, i.e. flat rectangular ingots from 1 to 2 inches in thickness. The tenacity of zinc as
st is about 1 ton per square inch, and its elongation is practically nil. Zinc, after compression
der a stress of 20 tons per square inch at 100° C., has a tenacity of about 11 tons per square inch.
It is ductile between 212° F. and 302° F. and can then be shaped as required. But when
her above or below these limits it becomes brittle and unpliant, and therefore not adapted for
eatment. It melts at about 786° F. if volatilisation is guarded against.

Impurities in Commercial Zinc.

Arsenic.

Arsenic is a common impurity in spelter. It does not occur in such quantity as to have a
leterious effect upon the mechanical properties of spelter or of such alloys as contain it. It
however, an objectionable ingredient in such zinc as is to be employed in the production of
drogen.

Cadmium.

Cadmium is nearly always present in zinc; in electrolytic varieties of the metal it rarely exceeds
)7 per cent., in other varieties as much as 0·40 per cent. is found. The effect of this element
to harden spelter and to make it more brittle. Cadmium is, on this account, objectionable
nen the zinc has to be rolled into sheet or to be used for galvanising telegraph wires. In zinc
the manufacture of brass subsequently to be cold-worked as much as 0·20 per cent. of
dmium may safely be allowed.

Copper.

Copper tends to harden zinc, but is rarely present in quantity sufficient to effect radical change
the metal.

Iron.

Iron hardens and embrittles zinc. Its presence tends to the formation of dross in the
lvanising process.

Such zinc as is to be used in the manufacture of cold-worked brass should not contain above
.0 per cent. of iron. Electrolytic spelters rarely contain above 0·025 per cent.; as much as
5 per cent. of iron is, however, to be found in certain zincs.

Lead.

Lead is present in certain brands of zinc up to 2·5 per cent. The purer brands of spelter contain
to 0·20 per cent. of lead. The presence of lead is not deleterious where the spelter containing it
to be used for general brass manufacture, but where brass is to be cold-worked or specially
ated care must be taken that the spelter used has not too high a content of lead.

Lead in moderate quantity tends to make zinc softer in rolling. When present in quantities
excess of 0·7 per cent. it tends to the production of serious cracks in slush castings of zinc.

Other elements occasionally present in spelter in traces are sulphur and carbon.

TIN.

The London Metal Exchange form of contract (1911) for the purchase of tin recognises tw classes of tin—Class A, tin assaying not less than 99·75 per cent. of pure metal; Class B, ti assaying not less than 99 per cent. of pure metal.

The tensile strength of cast tin varies (according to Thurston) from 2,000 to 6,000 lbs. pe square inch. The elongation is, for all practical purposes, nil.

The principal impurities in commercial tin are lead, iron, copper, and arsenic. Sulphur, silve bismuth, and antimony are of frequent occurrence.

NICKEL.

Nickel containing small quantities only of impurities is a commercial article. On account of it readiness to occlude carbon monoxide and other gases, and its affinity for carbon, it is difficult t obtain nickel in a pure state in the cast condition. Parker, experimenting on pure, dead soft wrought nickel, has arrived at the following figures for the mechanical properties of nickel:—

Elastic limit	6–10 tons per sq. in.
Maximum stress	18–20 ,,
Elongation	8–15 per cent.

Nickel Plating.

According to the American Bureau of Standards, if nickel plating be made considerabl thicker than is necessary or customary on brass parts, the protective value can be materiall increased. It is believed that 0·001 in. is the minimum thickness that should be employed.

Impurities in Commercial Nickel.

Carbon.

Carbon is present in nickel up to 0·20 per cent., though it rarely exceeds 0·15 per cent. It ha an embrittling effect on nickel when in the form of graphite, but when combined with nickel a nickel carbide it has a strengthening effect.

Cobalt.

Cobalt has a strengthening and hardening effect on nickel, but in the quantities—up to 1·0 per cent.—usually found in commercial nickel, this element has but little effect.

Copper.

Copper is similar to cobalt in its action, but rarely exceeds 0·20 per cent. in amount.

Arsenic.

Arsenic should not exceed about 0·025 per cent. in such nickel as is to be subjected to cold work, or in alloys for a similar purpose.

Iron.

Iron has an effect on nickel similar to that of cobalt and chromium, but, being rarely presen in quantities in excess of 0·75 per cent., its presence is scarcely noticeable.

Silicon.

As much as 0·30 per cent. of siliceous matter can be present in commercial nickel. Its effec on the properties of the nickel is uncertain.

Sulphur.

Sulphur is occasionally noted in samples of nickel.

Nickel, if it is to be satisfactory for the manufacture of copper-nickel alloys for cold-working, should be free from all unreduced oxides.

CHROMIUM.

The colour of chromium is silver-white. Nickel has a little more of a yellow tinge to it than chromium. On the other hand, chromium will hold its colour indefinitely. Nickel will turn almost black in a laboratory atmosphere, and chromium will stay bright indefinitely. It is about the only metal known that will stay bright in a laboratory atmosphere. Not even platinum will stay as bright. See also p. 2689.

Electro-Deposition of Chromium.

In an article in the *Iron and Coal Trades Review* Mr. C. H. S. Tupholme gives the following hints on the electro-deposition of chromium. The cathode used was of iron, the bath at atmospheric temperature, and no mechanical stirring was used. In these conditions the most satisfactory concentration was obtained at 245 grammes per litre of chromic acid together with 3 grammes per litre of chromium sulphate. With this solution standardised the effect of varying the current density over the range between 2·7 and 54 amperes per sq. dm. or 25 to 500 amperes per square foot was tried, and it was found that good deposits were obtained up to 16 amperes per square dm. or 150 amperes per square foot. Beyond this current density the deposits were not so satisfactory, as the deposits were dark in colour and ultimately exhibited a tendency to crack. To obtain a bright deposit the most satisfactory current density was found to be between 100 and 125 amperes per square foot, using the electrolyte at ordinary atmospheric temperature.

Sand and Die Aluminium Castings

are replacing cast brass and iron because they are stronger, one-third the weight, highly corrosion resistant, malleable and non-magnetic, machinable at 1,000 ft. per minute and hence

ALUMINIUM.

Aluminium which contains up to 99·9 per cent. of the pure element can be produced on a commercial scale, but the commercial metal is rarely above 99·5 per cent. pure. The impurities generally present in primary aluminium pig are: copper, iron, silicon, sodium, zinc, nitrogen, and a typical analysis is as follows:

Aluminium	99·57 (by difference)
Copper	0·0465
Iron	0·1973
Silicon	0·2246
Nitrogen	0·092
Sodium	trace
Zinc	0·0024

The mechanical properties of cast aluminium are as follows:

Elastic limit	3–4 tons per sq. in.
Maximum stress	5–7 ,,
Elongation	3–4 per cent.

The tenacity of hard-rolled aluminium can be as high as 18 tons per square inch.

Primary aluminium is not used in the cast condition for constructional purposes. It is used as a deoxidiser in the manufacture of steel, and in the form of powder and dust in the thermit process and in paint. The principal use is in the wrought form, such as sheets, tubes, mouldings, rods, wire, etc. As commercially pure aluminium has extensive application in the brewing and chemical industries, and also for domestic purposes, it is important to consider the action of acids upon it, which may be briefly stated as follows:

Hydrochloric Acid.—Attacked with great rapidity hot or cold and at all concentrations.
Hydrofluoric Acid.—Rapidly attacked.
Sulphuric Acid.—Attack slow with concentrated acid. Appreciably attacked with hot dilute acid.
Nitric Acid.—Attack very slow, the metal becoming passive (can be used for containers for cold strong HNO_3).
Acetic Acid.—Attack slow with cold acid, increases with use of temperature.
Lactic Acid.—Attacked very slowly (suitable for milk containers).
Oleic Acid.—Practically no effect.
Action of Air.—Attack very slow in fairly pure air, increases considerably in impure atmospheres. (The oxygen forms a thin film of oxide which tends to retard further action.)
Action of Alkalies.—Potassium and Sodium Hydroxide.—Rapidly attacked. Ammonium Hydroxide.—Attack slow. Alkaline Water.—Attacked appreciably by water in which alkalies or soap have been added.

Most metals will alloy with aluminium, but only a few definite alloys (aluminium—copper, iron, manganese, magnesium, nickel, silicon, tin, zinc) are used to a large extent. These include the binary alloys Al–Zn, Al–Cu, ternary alloys Al–Cu–Zn, Duralumin and related alloys, silicon and certain complex alloys. The so-called heavier alloys are the aluminium brasses and bronzes. Certain iron-aluminium bronzes and manganese-aluminium bronzes are also used.

Annealing Sheet Aluminium.

1. Prepare a mixture of ordinary whiting and oil, mixed to the consistency of thick paste. Coat the metal on both sides with this preparation, and place it on a clean fire or in a furnace. Allowing it to remain until the oil in the paste becomes ignited. When this occurs withdraw the work from the furnace and allow it to cool gradually. The coat of whiting should then be removed from the surface of the metal by washing and brushing.

2. Heat the metal to a dull red colour, perceptible in the dark, and cool slowly. With this method care must be exercised to get an equal annealing temperature distributed over the entire surface of the work.

3. Heat the sheet aluminium until pine-wood sawdust just glows when sprinkled on it, which indicates a temperature of about 750° F. At this temperature a dry match-stick will just char when rubbed on the metal. (*A. Eyles*, '*Machinery*,' *Aug.* 11, 1921.)

The Protection of Aluminium from Corrosion.

Aluminium and its alloys can be efficiently protected against atmospheric corrosion under the most severe conditions only by the use of an enamel or varnish paint. Oil paints are very inferior in protective power to those referred to above.

MAGNESIUM.

Magnesium, which is a lighter metal than aluminium, promises to play an important part in the future of light alloys, particularly for aircraft construction.

NON-FERROUS ALLOYS.

COPPER AND ZINC.

The alloys of copper and zinc containing over 50 per cent. of copper are generally termed 'brasses.' The mechanical properties of these alloys have been the subject of numerous investigations; in this connection such authorities as Thurston, Charpy, Lohr, Guillet, etc., should be consulted.

Below are given the results of Guillet's tests on the brasses. His tests were carried out upon material which was worked, then heated for ten minutes at 750° C. in a salt bath and finally cooled in air.

Alloy Composition.	Yield Point.	Max. Stress.	Elongation per cent. on 100 mm.	Hardness.
Copper.				
100 per cent.	2·09	14·28	52·5	48/49
98 ,,	1·64	14·41	58·0	48/50
96 ,,	2·59	15·27	57·5	52
90 ,,	3·54	16·43	54·0	55/58
85 ,,	3·35	16·43	58·0	57/58
80 ,,	4·17	18·52	72·0	60/63
75 ,,	4·49	19·47	77·0	60/62
72 ,,	4·69	19·59	77·5	60/61
70 ,,	4·65	19·59	73·5	60/64
67 ,,	4·49	19·02	72·5	56/60
65 ,,	4·69	19·25	73·0	62
62 ,,	6·59	23·06	57·0	80/81
60 ,,	6·95	23·76	50·0	81/82
58 ,,	4·27	25·15	51·0	92/95
56 ,,	7·33	21·06	40·0	121/131

Figs. 15 and 16 (pp. 2711 and 2712) show the relation existing between the mechanical properties of the pure brasses and their copper content.

The casting temperatures of these alloys are of exceptional moment. The following tests show the influence of varying casting temperature on the tensile properties of 40·5 per cent. zinc-copper alloy castings poured from one crucible within a short interval of each other. Chemically the three castings were identical.

Casting Temperature °C.	Maximum Stress Tons per Square Inch.	Elongation per cent.
1,038	12·45	6·0
943	16·28	9·5
934	18·88	15·0

In every case with other alloys similar temperature variations have a similar effect on the mechanical properties. The following results obtained from manganese bronze were obtained by Guillemin :—

Casting Temperature °C.	Maximum Stress. Tons per Sq. In.	Elongation per cent.
1,400	15·2	13
1,300	19·7	45
1,250	21·6	35
1,200	22·9	30

In judging a suitable pouring temperature the appearance of the alloy in ladle or crucible may be used as a guide. With manganese bronzes this appearance is somewhat confused by the aluminium present, for, as is well known, this imparts a characteristic skin to the surface of the molten alloy. The practical effect of this is to make the alloy appear colder and less fluid than is really the case. Careful observation readily overcomes this difficulty.

There is little doubt that the pyrometer is, in the hands of careful workers, the best means of determining the temperatures of metal or alloy in the ladle or crucible.

(See also Zinc-Tin Alloys, page 2730.)

Cast Brass.

Cast brass is somewhat variable in composition, but usually contains about 66 per cent. of copper, this percentage being that found in English standard brass.

FIG. 16.

The metals employed in the production of cast brass are not generally selected with such care as are those used in the manufacture of malleable brass. Lead, tin and iron are common impurities.

Lead in proportions varying from 1 to 3 per cent. is frequently added for the purpose of facilitating machining. It reduces the tenacity and hardness and increases the corrodibility of the resulting alloy, and is liable to segregate in those parts of the castings that solidify latest on cooling.

Tin tends to harden brass and is added in quantities up to 3 per cent., though 2 per cent. is not generally exceeded.

Iron hardens and increases the tenacity of brass.

The presence of more than one of these elements in quantity is to be deprecated, as their combined effects on the mechanical properties of the resulting alloy are likely to be injurious.

The mechanical properties of cast brass of average composition (66 per cent. of copper) and containing only small quantities of impurities or added elements are :—

Yield point, 6 tons per sq. in.; Tenacity, 14 tons per sq. in.; Elongation, 40 per cent.

A number of alloys, adapted for particular purposes, are tabulated below :—

Alloy.	Cu. Per cent.	Zn. Per cent.	Other Metals. Per cent.
Very delicate castings	86·00	14·00	—
Good yellow brass	75·00	25·00	Sn. 2·00
Name plates	86·00	9·00	Sn. 3·00; Pb. 2·00
Small castings (red)	90·00	10·00	,, ,,
Taps, cocks, etc.	78·00	14·00	Sn. 3·00; Pb. 3·00
Fine castings (yellow)	71·00	24·00	Sn. 2·00; Pb. 3·00
Hydraulic pumps	58·00	38·00	Sn. 2·00; Fe. 2·00

Ductile Brass.

The brasses containing upwards of 63 per cent. of copper are ductile and malleable at ordinary temperatures, provided that the metals used in the production of the alloys be of the best quality, and that the alloys be well annealed during working. The most suitable annealing temperatures for ductile brass are between 650° C. and 700° C.

Lead is admissible in alloys that are to be rolled into sheet, but is injurious in alloys that are to be drawn into wire. It should not be present in such quantity as is liable to create trouble at the annealing furnace.

The most ductile of the brasses contains 70 per cent. of copper and possesses the following mechanical properties when fully annealed subsequent to rolling :—

Yield point . . 10 tons per sq. in.; Elongation . . 60 per cent. on 2 ins.;
Maximum stress . 23 ,, ; Hardness (Brinell) 120.

Hot-forgeable Brass.

The alloys of copper and zinc containing from 59 to 61 per cent. of copper are characterised by their ability to withstand hot rolling at temperatures ranging from 500° C. to 800° C. They are employed in sheet form for the sheathing of wooden ships and in bar form for the manufacture of bolts, fastenings, etc. They are forgeable under the drop hammer and, hence, are frequently used in the manufacture of stampings. In this last connection it is particularly noteworthy that constancy of composition must be attained, on account of the large variations in machining properties accounted for by small changes in the copper content. The alloys in the range 57 to 63 per cent. of copper are forgeable, though not capable of withstanding rolling, in the temperature range already stated, and may be considered here.

All the above alloys are retained in a harder, stronger, and less ductile condition if quenched from temperatures between 750° C. and 800° C. than if allowed to cool slowly. They are liable to spontaneous cracking if worked at temperatures below 600° C., which liability, if thought to be inherent, can be lessened if the alloys are annealed at temperatures between 200° C. and 300° C., subsequent to working. The best temperatures for annealing, with a view to reducing variations in the mechanical properties due to variations in the mechanical and thermal treatment, are below rather than above 650° C. The temperature range (750° C.–800° C.) is, according to Stead, a dangerous one in which to conduct the annealing of hot-forgeable brass.

The average mechanical properties of fully annealed cast 60/40 brass are as follows :—

Yield point . . . 10 tons per sq. in.; Elongation . . . 35 per cent.;
Maximum stress . 25 ,, ; Hardness (Brinell) . 85.

Drawn rod of 60/40 composition is obtainable having the following average mechanical properties :—

Yield point . 28 tons per sq. in.; Elongation . . 20–30 per cent. on 2 ins.;
Maximum stress . 32 ,, ; Hardness (Brinell) 140.

The last factor appears to be dependent on the diameter of the rod in question, being least when the diameter of the rod is greatest. On account of the almost infinite variety of hot- and cold-working possible in the treatment of these alloys almost infinite variations in mechanical properties are obtainable.

Effect of certain Metals on Brass.

TIN.

Naval Brass.

Tin raises the tenacity, increases the hardness and resistance to corrosion and lessens the elongation of the 60/40 alloy, to which it is added commercially to make Naval brass. The latter contains 60–62 per cent. copper, 1–1½ per cent. tin, and the rest zinc. Not more than 2 per cent. of tin should ever be present; 4 per cent. induces great brittleness.

IRON.

Iron increases the tenacity and hardness of brass. The difficulty of dissolving iron in brass was first overcome by a special process, the invention of Dick (see also p. 2716), whose alloy, generally containing 55–57 per cent. copper, 42 per cent. zinc, 1–2 per cent. of iron and traces of phosphorus, is well known.

Iron is now generally added to brass in the form of ferromanganese, an alloy of iron and manganese which is readily dissolved in molten brass.

MANGANESE.

Manganese 'Bronze.'

Manganese is added to brass with a view to improve the mechanical properties of the same. The resulting alloys are divisible into two classes:

(*a*) Alloys in which either no manganese or traces only of manganese are present, i.e. alloys to which the element has been added for purposes of deoxidation.

(*b*) Alloys in which appreciable quantities of manganese are retained in solution. These may be subdivided into (i) such as are suitable for rolling into rod and containing up to 0·05 per cent. of manganese, and (ii) such as are suitable for casting and containing less than 60 per cent. of copper, and up to 2·0 per cent. of manganese.

The manganese is introduced into the alloys by the addition of ferromanganese or cupro-manganese.

These alloys are forgeable when heated to temperatures above 750° C. They resist the corrosive action of sea water, and are employed in the manufacture of ships' propellers. Iron, aluminium and tin are generally present in manganese 'bronze.'

The analyses of the alloys known under this name are varied in accordance with the character and nature of the purpose for which they are combined, and as the results depend entirely upon expert treatment in handling, we have obtained through the courtesy of the Manganese Bronze and Brass Co., Ltd., London, the tests on manganese bronzes recorded below.

TESTS OF MANGANESE BRONZE (CARRIED OUT BY MESSRS. BURSTALL & MONKHOUSE AT THEIR LABORATORY IN WESTMINSTER.)

STEAM CASTINGS—FOR SUPERHEATED STEAM.

Test.	Maximum Stress Tons per sq. in.	Yield Point Tons per sq. in.	Elongation in 2 ins. Per cent.

Crotorite Bronze.

This new alloy, one of The Manganese Bronze & Brass Co.'s specialities, is zinc free, of steel-ce qualities, and particularly recommended for bars and forgings exposed to corrosive fluids and igh temperatures.

Delta Brand Alloys.

The metals and alloys sold by the Delta Metal Co., Ltd. (of London and Birmingham), under heir registered trade-mark 'Delta,' are employed for a very great variety of purposes, the omposition varying widely according to the requirements and purposes for which each of these etals or alloys is more particularly adapted. Some of them are based upon the introduction nd chemical combination of definite quantities of iron and other elements in copper-zinc alloys. he effect of iron on brass has already been noted; the difficulty of introducing it in definite uantities was first overcome by the late Mr. Alexander Dick, the founder of the Delta Metal o., Ltd., who adopted the name 'Delta' (the Greek equivalent of the initial letter of his name) s a trade-mark. In most of the alloys which may be classed under the 'Brasses,' the copper ontent lies between 57 and 62 per cent., that of zinc between 42 and 38 per cent., whilst some ontain iron, phosphorus, manganese, or other metals, up to a total of about 2 per cent.

The following alloys, designated by the trade name 'Delta,' and manufactured by the Delta etal Co. Ltd., find wide application.

Delta Bronze Nos. I and IV are practically incorrodible, and consequently of very great urability, even when used in strongly corrosive mine-waters, etc.; they are not attacked by sea-

water, and resist acids much better than other copper alloys. On account of their great strengt and resistance to corrosion, these alloys are largely used for parts of marine engines an mining and hydraulic plant which require a strength not less than that of the best steel, but the same time freedom from corrosion—such as pump rods, piston rods, shafts, cranks, plunger spindles, rams, etc. For propellers and propeller blades, Delta bronze is in great demand, and is also successfully used for parts of ordnance, etc.

These alloys are malleable bronzes of very great strength, exceeding, even in the cast stat the strength of mild steel. They can be cast with facility, and will produce perfectly sound an homogeneous castings. When heated to a dull red heat, they become soft and highly malleabl and can then be readily forged, stamped, rolled, or pressed, to any extent required. These oper tions increase the strength considerably, as will be seen by the following copies of tests.

Description of Metal.	Diameter. In.	Area. Sq. in.	Ultimate Strength. Tons per sq. in.	Elongation in 2 ins. Per cent.	Reduction of Area. Per cent.

Extruded bar .	0·500	0·1963	37·1	27·0	20·0

Extrusion Process.

The process of extruding copper and its alloys, the invention of the late Mr. Alexander Dic developed and worked by the Delta Metal Co., Ltd., of London and Birmingham, under numero subsequent new patents and improvements, consists of the pressing or squeezing of heat metals through dies of any desired cross-section, by hydraulic pressure varying according the section to be produced and the character of the metal operated upon.

Dick's extruded bars have a perfectly smooth and uniform surface, free from cracks or oth defects; size and shape are of the greatest accuracy, and owing to their superior finish, machini is reduced to a minimum. The Company are able to produce extruded rods as ordinary round pinion wire weighing a fraction of a pound per foot per run, to heavy round, square or hexag rods, or other sections, more or less complicated, weighing as much as half a cwt. and over per foo The facility of manipulation ensures rapid output, so that sections not regularly kept in stock c be supplied at very short notice.

The Delta Metal Co., Ltd., are not only the original, but claim to be also the largest man facturers of extruded rods and sections. They supply these in various metals and alloys: 'Delta' bronzes Nos. I, II, IV, and VII, Heagard bronze, manganese and aluminium bronz brass, yellow metal, naval brass, etc.

They make a speciality of high-speed turning and screwing brass ('Delta' Brand a 'Dixtrudo' Brand) in every variety of shapes and sections. This material, like the stampin and pressings in brass, bronze, and copper made by the Delta Metal Co., Ltd., is used large for repetition work and mass production, and supersedes castings.

Bull's Metals.

(Bull's Metal & Melloid Co. Ltd., Glasgow.)

Bull's Metals are strong, malleable alloys of good casting qualities, and equal to good gunmet in resistance to corrosion. They are manufactured in two qualities, No. II and No. III.

Alloy No. II is suitable for founding purposes, and extensively used for propellers and pr peller blades, parts of guns and gun carriages, requiring the strength of cast steel with gre toughness and resistance to corrosion.

Alloy No. III is very malleable and can be rolled, forged, stamped, or otherwise wrought at red heat; this metal also casts well. Its composition ensures great resistance to corrosion a wear. It is absolutely non-magnetic.

Rolled in round, hexagon, angle, and section bars, or into sheets and plates; forged stamped Bull's metal is used for pump rods, centrifugal pump spindles, rams, stern shaft sluice valve spindles, parts of marine and hydraulic machinery generally. Forged propell blades, propeller studs and nuts. Bolts, nuts, screws, studs, and nails. Parts of torpedo and torpedo boats, ordnance, ammunition, etc. Condenser plates, strainer plates, doct blades. Hull plates and angles for launches, torpedo boats, yachts, sailing and rowing boa

The elastic and ultimate resistance to tensile, crushing, and torsional stresses are greater in t case of wrought Bull's metal than in mild steel, and higher working strains may therefore be us with Bull's metal. Where resistance to the action of water or chemicals enters as an importa factor, Bull's metal, whether wrought or cast, becomes specially superior to steel.

TENSILE TESTS OF BULL'S METALS.

Dimensions.	Area. Square inch.	Reduction area at fracture.	Extension.	Ultimate Stress.	Remarks.

0·688	0·3717	30·6	29·0 on 6 ins.	31·47	Cast medium.
0·750	0·4418	24·2	22·0 on 3 ins.	38·68	Cast hard.

'MELLOID.'

(Registered Trade Mark.)

This alloy is a malleable genuine bronze containing no inferior metal; its resistance to corrosion very great. Its tensile strength in a rolled state when suitably finished is as high as that of mild eel; the strength is not appreciably affected at the temperature of high-pressure steam, whilst pper at such heat is very much reduced in strength and elasticity.

The alloy is perfectly malleable at *all* temperatures, from cold to blood-red heat; it has no ittle stage at a black heat like most metals and alloys, and at a red heat it is much superior in ength and toughness to mild steel under such conditions, and the alloy, under all conditions, is ceedingly tough.

'Melloid' meets the mechanical requirements referring to copper, naval brass, and rolled onze specified by the Admiralty, the principal railway companies, and consulting engineers.

It is claimed that 'Melloid' will be found superior to all brass alloys, including naval brass, llow or Muntz metal, and also to wrought copper, wherever a combination of toughness, eat strength, and a maximum resistance of corrosion is required.

NICKEL ALLOYS.

Nickel Silver.

The alloys of copper, nickel and zinc containing from 45 per cent. to 65 per cent. of copper, per cent. to 30 per cent. of nickel and 15 per cent. to 25 per cent. of zinc are of commercial portance and are classified under the general title of 'nickel silver.' The metals employed the manufacture of these alloys must, if the same are to be used in the production of cold-rked articles, be of the highest degree of purity. For the manufacture of castings, metals a lesser purity may be used.

Lead, tin, iron and unreduced oxides are the impurities generally present in nickel silver. ad is occasionally added to nickel silver in quantities up to 3 per cent. when the same is to employed for casting. Tin in quantities upwards of 2 per cent. has a hardening and em-ttling effect on the alloy, while iron in similar quantity has a hardening effect only. The dition of any of these elements results in injury rather than benefit to the alloys and especially reases the corrodibility of the same.

The effect on the mechanical properties of nickel silver of almost constant copper content increasing the nickel content has been admirably shown by Thompson (Institute of Metals, rch 1916), from whose paper on 'The Annealing of Nickel Silver' the following table is taken :—

TENSILE TESTS ON CAST BARS.

Cu.	Zn.	Ni.	Mn. added.	Yield Pt. Tons per sq. in.	Maximum Stress. Tons per sq. in.	Elongation. Per cent. on 2 ins.	Reduction of area. Per cent.
60·6	31·7	7·6	—	7·16	16·88	34·5	37·2
60·2	31·8	7·8	0·25	6·60	15·28	46·5	46·9
61·8	21·7	16·4	—	9·00	17·80	39·5	32·7
61·2	23·2	15·5	0·25	8·12	18·36	39·0	45·9
61·6	15·9	22·4	—	8·52	17·20	24·5	26·7
61·6	18·5	19·8	0·25	8·24	19·36	32·5	33·5
55·7	26·7	17·4	—	9·04	17·12	33·5	37·8
54·3	29·7	15·8	0·25	8·92	16·88	38·5	40·0
56·2	27·6	16·3	1·50	9·04	17·96	44·0	41·1
61·2	9·8	28·6	—	8·76	19·72	32·0	36·7
60·4	11·4	27·9	0·25	10·32	23·68	29·0	29·7
60·9	13·2	26·7	1·50	10·88	24·16	35·0	33·1

Other results of his research show that the tendency of commercial nickel silver to 'burn increased (*a*) by increasing the nickel content, (*b*) as the ratio of the zinc to the copper increased, and (*c*) with the amount of impurities present.

The following alloy is stated to be possessed of the best all-round properties :—

Copper, 46 per cent. ; Nickel, 39 per cent. ; Zinc, 20 per cent.

Monel Metal.

This is a natural nickel alloy which resists corrosion and has a high tensile strength. It mined in Ontario, Canada, and is smelted and refined under careful technical control witho separation of the virgin metals.

It has an average composition of :

Nickel . . . 67 per cent. Copper . . . 28 per cent.

and contains iron, manganese, carbon, etc., but no tin, lead, or antimony.

Its physical characteristics are as follows :

Melting point, 1300° C.	Heat conductivity, $\frac{1}{15}$th that of copper.
Specific gravity, 8·87.	Brinell hardness :
Weight per cu. in., ·323 lbs.	Cast material, 120 to 140.
Co-efficient of expansion, ·0000137 per 1° C.	Hot rolled rods and sheets, 150 to 190.
Shrinkage allowance for castings, $\frac{1}{4}$ in. per foot.	Izod test, 107–115 ft.-lbs. (unbroken).

The average tensile strength and elongation : hot rolled rods, 35–40 tons per sq. in., elongatio 36–51 per cent. ; hot rolled sheets, 30 tons per sq. in., 15–40 per cent. ; castings, 19–25 tons p sq. in., 10–20 per cent.

The hardness and tensile strength of Monel Metal can be greatly increased by cold drawing. Brinell of 237 and a tensile strength of 58 tons have been obtained in this way.

Monel metal is used on account of its great strength at high temperatures for equipmer controlling superheated steam, *e.g.* valves, valve seats, valve stems, turbine blading, nozzle condenser tubes, etc., and, on account of its resistance to corrosion, for pump rods, spindl and impellers, etc. ; also, because of its great resistance to acids and alkalies, for jacketed pan dyeing machines, etc. ; and, on account of its ornamental appearance, for shop fronts, counter and hotel, restaurant and hospital equipment—such as tables, urns, sinks, dish-washing machine cooks' tables, hoods, and canopies, operating tables, sterilizing drums, basins, shelves, etc. ; it available in all general engineering forms.

Platnam.

Consists of 54 per cent. nickel, 33 per cent. copper, and 13 per cent. tin. It is used for th manufacture of valve seats and valves which have to withstand the action of superheated steam.

Nickel Chromium.

These alloys have a composition which varies considerably according to the purpose for whic they are required, but in those of commercial utility the nickel content lies within the limits o 60 per cent. and 80 per cent. and the chromium content between 12 per cent. and 22 per cen The balance consists mainly of iron, with small percentages of manganese, silicon, aluminium and carbon, other elements being present only as traces of impurity.

A typical alloy has the approximate composition of nickel 66 per cent., chromium 20 pe cent., iron 10 per cent., the balance consisting of the above-mentioned minor components.

Physical Properties.

Tensile strength in cast state . . .	25 to 30 tons per sq. in.
Melting-point	1300° to 1350° C.
Density	·29 lbs. per cu. in.
Specific heat	·11

These alloys have two outstanding properties which have great commercial value, namely their strength is well maintained at high temperatures, and they are chemically inactive under a wide range of conditions even at high temperatures. Thus they resist the attack of furnace gase to a marked degree, and unless sulphur is present in unusually large quantities, their life at tem peratures up to 1200° C. is very considerable.

The actual life of articles made of this alloy is greatly dependent upon conditions, but a perio approaching 10,000 hours at such temperatures is by no means unusual.

The above properties make the alloys eminently suitable for the manufacture of such article as pyrometer sheaths, case-hardening boxes, furnace parts, retorts, muffles, in which rôles they have been of great assistance to engineers in overcoming difficulties due to the severe condition of temperature and corrosion which modern works practice produces.

Such alloys have long been recognised, when drawn into wire or rolled in strip form, to be tremely valuable for such electrical purposes as windings for electric furnaces and stoves.
The alloys are frequently of service to chemical engineers for use with corrosive fluids at rmal temperatures, and have found application in the manufacture of such articles as acid mps and valves subject to attack by acids and acid vapours.
An alloy designated the 'Emperor' chrome nickel alloy is manufactured by Messrs. Sutcliffe, eakman & Co., Ltd., and is of great durability.
A large number of pyrometer tubes, case-hardening boxes, and similar utensils made of the oy are in use in some of the principal works of the country.

Platinite.

Platinite is an alloy of iron, nickel, and carbon, which is used extensively for scientific instruments for standard measurements of length because of its peculiar quality of being practically n-expansive when heated to high temperatures. It is also used in incandescent electric lamps ere the wire connections fused into the glass must have so small a coefficient of expansion not to cause fracture in the glass. This alloy contains about 46 per cent. of nickel and 54 per t. of iron, with a very small percentage (0·15 per cent.) of carbon.

A Platinum Substitute.

A white alloy, 'Palorium,' says *Industrial and Engineering Chemistry*, is very difficult to tinguish from platinum in appearance. The temperature co-efficient, hardness and tensile ength of the alloy compare not unfavourably with those of platinum. The alloy is ductile, lleable, and homogeneous, it melts at 1,310° C., and is superior to platinum in its resistance the action of potassium hydroxide fusions and concentrated sulphuric acid. The loss in ght of a specimen subjected to the action of concentrated hydrochloric acid was only 0·9 ligram after 40 minutes, and after 1 hour, 1·0 milligram, so that its powers of resistance are se enough to those of platinum to make it a desirable substitute.
Another property of the material, and one which is of considerable advantage for plant or oratory use, is that it retains its stiffness when heated and does not soften like platinum. orium gives excellent results in electrolytic determinations, but is only suitable for the cathode. is obtainable in commercial form as crucibles, dishes, sheet, wire, and contact points, while cost of the manufactured article is some 45 per cent. less than where platinum is employed.

Platinoid.

Platinoid, introduced by Mr. F. W. Martin, is a kind of German-silver, with an addition l to 2 per cent. of tungsten. The latter, in the form of phosphor-tungsten, is first melted ether with a certain quantity of copper. In order to remove the phosphorus and a part of tungsten, both of which separate dross, the resulting compound is several times remelted. ally an alloy of a beautiful white colour is obtained, which when polished closely resembles er, and retains its lustre for a long time. Platinoid has the properties of German-silver a pre-eminent degree. It shows great electrical resistance, which remains almost constant ifferent temperatures, and is about 1½ greater than that of German-silver.

ALUMINIUM.

Aluminium Brass.

Aluminium acts as a deoxidiser and is added to cast and hot-forgeable brass, for the purpose nproving their mechanical properties, in quantities varying from 0·3 to 1·5 per cent.
Typical tests of cast aluminium brass, containing 38 per cent. of zinc, 2 per cent. of aluminium, 2 per cent. of lead, are :—

Yield point	18 tons per sq. in.
Maximum stress	34 ,,
Elongation	12 per cent.

Melting Points of Commercial Brasses.

(*Gillett & Norton.*)

	Copper.	Zinc. (as desired).	Tin.	Lead.	Copper.	Zinc. (by analysis).	Tin.	Lead.	No. of Tests.	Melting Point.
brass	85	5	5	5	—	—	—	—	8	970°C.
-grade red brass	82	10	3	5	81·5	10·4	3·1	5·0	4	980°C.

COPPER AND TIN ALLOYS.

Gun-metal.

The alloys of copper and tin containing upwards of 86 per cent. of copper are possessed high tenacity and elasticity. Those containing from 89 to 91 per cent. of copper are the mo important and are known as ' gun-metals.'

The addition of tin to these bronzes results in an increase in the hardness of the resulti alloy. Gun-metal is rarely manufactured from specially selected metals and frequently contai lead, zinc, etc. The Admiralty specification for gun-metal is as follows :

Copper	88 per cent.
Tin	10 ,,
Zinc	2 ,,

the specified tests for this material being

Maximum stress	14 tons per sq. in.
Elongation	7½ per cent.

Gun-metal containing 90 per cent. of copper and 10 per cent. of tin should give the followi tests :—

Yield point	7 tons per sq. in.
Maximum stress	15 ,,
Elongation	15 per cent. on 2 ins.

Bell-metal.

The alloys of copper and tin containing from 75 to 86 per cent. of copper are used in the man facture of bells ; iron, zinc and lead are frequently added to the alloys either for cheapness variety of tone.

Effect of Certain Elements on Bronze.

ZINC.

Gun-metal, Bearing Metal, etc.

The alloys of copper, tin and zinc are rarely, if ever, free from elements such as lead, iron, et These alloys may be divided into two classes :—

(i) Alloys containing from 7 to 12 per cent. of tin, up to 6 per cent. of zinc, and up to 2 per cent. of lead. These alloys, among which may be noted gun-metal to the Admiralty specific tion, are used in the manufacture of castings, such as cocks, stuffing-boxes and pump barre and for bearings which are subject to but little friction.

(ii) Alloys containing from 12 to 20 per cent. of tin, up to 5 per cent., though rarely more th 2·5 per cent., of zinc and up to 5 per cent. of lead. These alloys are used in the manufactu of heavy bearings, e.g. railway wagon and locomotive axle boxes. The majority of alloys of th class contain from 14 to 16 per cent. of tin and from 1·5 to 2·5 per cent. of zinc.

Zinc combines with the oxides and free oxygen of the bronzes, producing greater fluidi in the molten state, and hence freedom from ' pinholes ' in the solid state.

LEAD.

Bearing Metal, etc.

The best bronzes should contain not more than 0·15 per cent. of lead, on account of its del terious effect on the mechanical properties of these alloys generally.

Bearing metals having a bronze matrix and containing up to 40 per cent. of lead are in comm use. A usual composition for bearings of this type is :—

Copper	64 per cent.
Lead	30 ,,
Tin	5 ,,
Nickel	1 ,,

The nickel is added to prevent the liquation of the lead. It increases the rate of cooling the alloy and thus assists in the retention of the lead in the finely divided form.

Lead does not alloy with bronze, but separates out of the molten mass, as the same cools, the form of globules. The lead bronzes may, therefore, be considered to consist of a netwo of bronze whose meshes enclose the lead content of the alloys in question.

PHOSPHORUS.

Phosphor Bronze.

Phosphorus acts as a deoxidiser and is added in small quantities for the purpose of deoxidation to copper. Not more than 0·15 per cent. is allowable.

The term 'phosphor bronze' is applied to the alloys grouped below.

(i) Bronzes to which phosphorus has been added as a deoxidiser and containing either no phosphorus or merely traces of the element.

(ii) Bronzes containing less than 9 per cent. of tin and up to 0·25 per cent. of phosphorus. These alloys are forgeable and are relatively non-corrodible. They are employed for rolling and drawing into wire and rod, and in the manufacture of general castings; in the latter case lead is occasionally added in quantities up to 5 per cent. The forgeable alloys of this group generally contain less than 5 per cent. of tin.

(iii) Bronzes containing from 8 to 14 per cent. of tin and from 0·25 per cent. to 1·00 per cent. of phosphorus. These alloys are employed for casting purposes in the manufacture of machine parts likely to be exposed to great friction. Lead up to 5 per cent. is added in certain cases.

Phosphorus is added to these alloys in the form of phosphor copper or phosphor tin.

The tensile strength of phosphor bronze varies from 14 to 18 tons per square inch, and the elongation from 6 to 10 per cent.

'Delta' Brand Alloys.

(The Delta Metal Co. Ltd.)

Delta Bronze No. V is an improved bearing metal of great strength and durability, and comparatively low price. It is particularly suitable for reducing friction at heavy pressures and high speeds, and is used for worm wheels for large cranes and other heavy machinery, hot neck rolls, locomotive slide valves, axle box, coupling, and connecting rod bushes, railway and carriage bearings, bushes, sliding surfaces, and other parts of machinery subject to heavy frictional wear. The metal is easy to tool, and requires no special precautions in casting.

Another metal used in lieu of phosphor bronze or gun-metal is 'Delta' Bronze No. VI, which produces fine, close-grained castings of great strength.

Melting Points of Commercial Bronzes.

(Gillett & Norton.)

	Copper.	Tin. (as desired).	Lead.	Zinc.	Copper.	Tin. (by analysis).	Lead.	Zinc.	No. of Tests.	Melting Point.

Bronze with zinc	85	10	—	5	84·6	19·4	—	5·0	4	980°C.

COPPER AND ALUMINIUM ALLOYS.

Aluminium Bronze.

The alloys known as the 'aluminium bronzes' are solid solutions of copper and aluminium containing not less than 88 per cent. of copper. Of these alloys that containing 10 per cent. of aluminium is the strongest, though the alloys containing less than this percentage are of industrial importance. These 'bronzes' are of use, firstly, on account of their valuable mechanical properties and, secondly, on account of their resistance to corrosion. They are malleable both when hot and when cold; the alloys containing between 8 and 12 per cent. of aluminium are affected in a marked degree by heat-treatment.

Following are tabulated the mechanical properties of some of these alloys:—

Percentage of Aluminium.	Yield Point. Tons sq. in.	Max. Stress. Tons sq. in.	Elongation. Per cent. on 4 in.	Remarks.
2·5	—	20·0	40·0	Cast.
5·0		25·0	55·0	Cast.
10·0	18·0	35·0	25·0	Cast in chill.
10·0	18·0	46·0	25·0	Cast rod reduced 25 per cent. by forging hot. Annealed.
10·0	15·0	40·0	30·0	Rolled bar.
10·0	40·0	50·0	3 0	Rolled bar quenched at 900° C.

The following are tests of the 'R3' and 'R4' aluminium bronzes, manufactured by the British Aluminium Company:—

R3 Bronze.—Average breaking load, 34·04 tons; average elongation, 21 per cent.; maximum

breaking load, 37·6 tons; maximum elongation, 35 per cent.; minimum breaking load, 32·8 tons minimum elongation, 12·5 per cent.

R4 Bronze.—Average breaking load, 41·8 tons; average elongation, 9·75 per cent.; maximum breaking load, 43·7 tons; maximum elongation, 13 per cent.; minimum breaking load, 39·8 tons minimum elongation, 6·5 per cent.

COPPER AND MANGANESE ALLOYS.

Manganese Bronze, Manganin.

The term 'manganese bronze' is applied to copper-zinc alloys of 60/40 composition to which small quantities of manganese have been added (see Manganese Bronze, p. 2714). There are, however, alloys of copper and manganese of industrial application which rightly should be admitted under this heading. The alloys of copper and manganese containing up to 5 per cent of the latter element are harder and tougher than is copper. Those containing from 2 to 4 per cent. of manganese are frequently employed in situations where high temperatures are existent on account of their retention of their mechanical properties under these conditions.

The following figures represent the results obtainable by stamping certain of these alloys at a red-heat (*circa* 800° C.):—

Copper.	Manganese.	Maximum Stress.	Elongation. Per cent.
97	3	18·5	32
96	4	21·0	60

Manganin is the name applied to an alloy of copper, manganese, nickel and iron, characterised by low electrical conductivity and almost zero temperature coefficient. It is employed in the construction of electrical resistance coils. The composition is somewhat variable, but the following figures will serve to indicate its approximate analysis:—

Copper	80 to 84 per cent.	Nickel	up to 12 per cent.
Manganese	4 to 15 ,,	Iron	Difference.

COPPER AND NICKEL ALLOYS.

Cupro-nickel, Constantan, etc.

The alloys of copper and nickel containing upwards of 50 per cent. of copper are of industrial importance. The alloys may be divided into three classes.

(i) Alloys containing up to 5 per cent. of nickel and having the property of resisting high temperatures without undue deterioration. Of these alloys those containing from 2 to 3 per cent of nickel have been employed in the manufacture of locomotive firebox tubes. Following are the mechanical properties of the 2 per cent. alloy:—

Maximum Stress.	Elongation. Per cent.	Remarks.
45·0	5·0	Hard rolled.
30·0	45·0	Hard rolled and annealed at 650° C.

Those of the 5 per cent. alloy are very similar in character.

(ii) Alloys containing from 15 to 25 per cent. of nickel and valuable on account of their ability to withstand cold working.

For the best results with these alloys only the purest metals should be employed, as small quantities of such elements as iron, silicon and sulphur are detrimental to the malleability and ductility of the resultant alloy. The maximum percentages of impurities allowable in nickel for this high-class work should be 0·050 per cent. of arsenic, 2 per cent. of cobalt, and 1·5 per cent. of other metallic impurities. The metal should be free from all unreduced oxides. Cupro-manganese, 25–50 per cent., is commonly employed as a deoxidiser in the manufacture of these nickel copper alloys, upwards of 0·25 per cent. being added to charges containing 30 per cent. of scrap. Following are the mechanical properties of the 20 per cent. alloy:—

Maximum Stress.	Elongation. Per cent.	Remarks.
40·0	5·0	Hard rolled.
20·0	35·0	Hard rolled and annealed.

The alloy containing 25 per cent. of nickel has been successfully employed in the manufacture of firebox plates.

(iii) Alloys having low electrical conductivities and whose temperature coefficients of electrical conductivity are practically nil. The 40–45 per cent. nickel alloy, known as 'constantan,' can be drawn into wire, and is employed in the construction of resistance coils and base-metal thermo-couples. Another alloy of this type, containing only 25 per cent. of nickel and 0·5 per cent. of iron, is known as 'nickeline.'

ALUMINIUM AND ZINC ALLOYS.

The alloys of aluminium and zinc are of importance as light alloys, their specific gravities varying uniformly from 2·7 to 3·3 as their zinc content increases up to 30 per cent., which may

be considered the limiting percentage for those alloys of this series that may be termed 'light.' All those alloys containing upwards of 70 per cent. of aluminium are forgeable at temperatures between 300° C. and 400° C.

These alloys do not allow of their use in casting into intricate shapes, but for all plain casting purposes they are quite satisfactory. Under certain conditions these alloys corrode rapidly; the use of high-grade spelter in their manufacture eliminates this defect. The machining properties of these alloys improve as the zinc content increases.

Below are tabulated certain of the results of tests reported by Messrs. Rosenhain and Archbutt to the Alloys Research Committee of the Institution of Mechanical Engineers.

Zinc. Approx. Per cent.	Condition of Alloy.	Yield Point. Tons per sq. in.	Max. Stress. Tons per sq. in.	Elongation. Per cent. on 2 ins.
5	1	2·70	5·20	16·0
	2	2·80	6·60	29·0
	4	4·30	7·48	33·0
11	1	6·40	9·41	8·0
	2	5·00	10·24	16·0

1. Sand-casting.
2. Chill-casting.
3. Hot-rolled bars, $\frac{1}{2}$ in. diam.
4 ditto $1\frac{1}{2}$ in. diam.

The addition of copper to certain of the aluminium-zinc alloys improves the mechanical properties of the same. The average results of certain tests on chill-castings of the aluminium-zinc-copper series are given below.

Zinc. Per cent.	Copper. Per cent.	Yield Point. Tons sq. in.	Max. Stress. Tons sq. in.	Elongation. Per cent.
19	1	9·5	14·9	5·5
19	2	12·5	16·5	5·7
20	2	10·4	14·0	3·3
20	3	11·5	16·8	4·5
20	4	10·4	15·3	3·8

ALUMINIUM AND COPPER ALLOYS.

Like the zinc alloys, the commercial alloys are not simple binary alloys, but generally contain iron and silicon, and may also contain Mg, Mn, Ni, Zn, etc.

Al.	Cu.	Use.
91·5	7–8·5	General castings.
92	8	General castings, tendency to be brittle.
96	4	General castings, less brittle than 92 : 8 alloy; suitable for rolled sheets, sand-cast cooking utensils.
89·5	9–10·5	Light alloy pistons } American automobile practice.
86·5	11–13·5	Manifolds }
90	10	Die castings. Permanent mould castings.
88	12	
50	50	'Hardness' or rich alloys; not used for constructional purposes, but used in the foundry for the purpose of introducing copper into aluminium or aluminium into copper.
60	40	

(See 'Aluminium Bronze,' p. 2721.)

The specific gravity increases with increase of copper from 2·7–2·85 for sand-cast alloy for 0–8 per cent. copper. The specific gravity of sand-cast alloys is less than that of chill casting and that of rolled and drawn alloys is approximately equal to chill cast. In sand-cast alloys th strength increases with increase of copper at the expense of the elongation. In the hot-rolle condition the tensile strength increases up to about 6 per cent. copper and then decreases. Th physical properties of these alloys are indicated by the following figures :

92–8 alloy. Ultimate strength, 18,000 lbs. per sq. in.; elongation, 1–1·5 per cent.

97–3 alloy (forged). Yield point, 16,000 lbs. per sq. in.; ultimate strength, 24,000 lbs. p sq. in.; elongation, 4 per cent.

96–4 alloy (rolled, annealed). Ultimate strength, 15,000–28,000 lbs. per sq. in.; elongatio 34–16 per cent.

Tensile strength of hot-rolled bars, 21,000–37,000 lbs. per sq. in. (for 1–6 per cent. copper elongation varies from 30–18 per cent. For cold-drawn bars—tensile strength, 29,000–45,000 lb per sq. in. (for 1–4 per cent. copper); elongation, 14·5–6 per cent.

ALUMINIUM AND SILICON ALLOYS.

A striking property of these alloys is their low contraction, due to the silicon expanding freezing. Yield exceptionally sound sand castings. Iron should be a minimum, as it has a deti mental effect. The specific gravity of these alloys is less than that of aluminium. Strength an elongation good, but the yield point is rather low.

These alloys appear under the trade name of 'Alpax' in America, and 'Silumin' and 'Alada on the Continent.

Method of preparation of these alloys has a great effect upon their properties. (1) Norm alloy, made by simply melting together aluminium and zinc. (2) Modified alloy, made by direc electrolytic reduction or by the addition of an alkali fluoride or with sodium or potassium to th melted normal alloy.

The silicon in (1) appears as relatively large plates, and in (2) in high dispersion.

For 'normal' castings—composition, 95–90 Al, 5–10 Si.

For 'modified' castings—composition, 90–85 Al, 10–15 Si.

The simple Al–Si alloys are difficult to machine, and Al–Cu–Si alloys have been developed overcome this.

OTHER ALLOYS OF ALUMINIUM.

Magnalium.

Magnalium is the name applied to a series of alloys having an aluminium-magnesium bas containing from 1·5 to 10·0 per cent. of magnesium and varying proportions of other element *e.g.* copper, tin, nickel, lead.

The table below gives the analyses of certain of these alloys, together with the uses to whi they are generally put.

Use of Alloy.	Magnesium.	Copper.	Nickel.	Tin.	Lead.
Strong castings . .	1·60	1·76	1·16	nil	nil
General ditto . .	1·60	1·76	nil	traces	traces

'Vickers' Duralumin.'

(*James Booth & Co. (1915) Ltd.*)

'Vickers' Duralumin' is the trade name applied to a series of quaternary alloys of aluminiu copper, manganese and magnesium, containing over 90 per cent. of aluminium and possessed high tenacity and hardness. The presence of magnesium confers the property of cumulativ hardening on certain aluminium alloys—*i.e.* subsequent to suitable thermal treatment the har ness of the alloy increases slowly to a maximum, which is attained after several days.

Following are typical analyses of 'Vickers' Duralumin' :—

Copper.	Manganese.	Magnesium.	Silicon.	Iron.	Aluminium.
3·62	0·35	0·87	0·62	0·045	Diff.
3·00	1·00	2·00	—	1·000	Diff.
3·60	0·40	—	0·50	0·600	Diff.

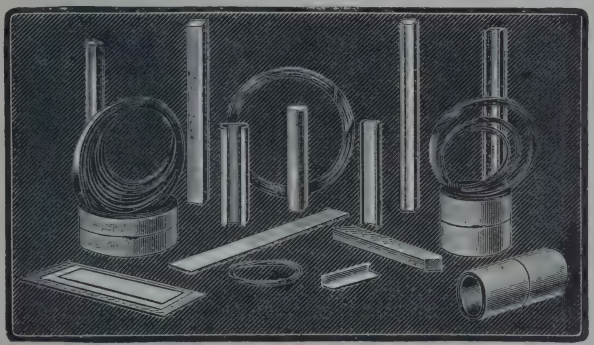
The specific gravity varies between 2·77 and 2·84. The melting point is about 650° ('Vickers' Duralumin' can be rolled, forged, and drawn when hot or cold. According to th purpose for which it may be required, the composition can be modified and the treatment s

"Vickers" Duralumin"

(REGISTERED TRADE MARK)

SPECIFIC GRAVITY 2·8 | **TENSILE STRENGTH UP TO 35 TONS**

AN ALLOY OF ALUMINIUM WITH THE STRENGTH AND HARDNESS OF MILD STEEL BUT HAVING ONLY ONE-THIRD OF ITS WEIGHT



It is an ideal substitute for Aluminium, Nickel, Brass, Copper, Nickel-plated and Silvered Articles, and is the only substitute for Steel where Lightness combined with the Strength of that Metal is required.

For Aeroplanes, Dirigibles Hydroplanes, Motor Car Yacht and Boat Fittings.

For Scientific Apparatus, Instruments of precision, Orthopædic Apparatus, and Hospital Supplies, etc.

A SET OF TANK ENGINE MAIN BEARINGS & CONN. RODS

ENGINEERS · and · MANUFACTURERS · of · AERO · and · MECHANICAL · TRANSPORT · ENGINE · PARTS ·

CONN. RODS, CRANK SHAFTS etc CONN. ROD and MAIN CHAIR BEARINGS WITH STEEL, PHOSPHOR-BRONZE or GUN-METAL SHELLS, WHITE-METAL LINED. Also SOLID WHITE METAL DIE, CAST UNDER PRESSURE AT LOW TEMPERATURES, ACCURACY GUARANTEED.

SOLE MAKERS of J. RICHARDS "PLASTIC METAL" for lining all kinds of bearings.

J. H. RICHARDS & Co. SPECIALITY.

We also manufacture solid whitemetal bearings, known as **Chill Cast Bearings,** which have come much into use during the last four years for Petrol Engines, also for Gas and Oil Engines. They show a great reduction in cost over the old method of lining a gun-metal shell, with whitemetal, which required machining all over.

These Chill Cast Bearings are supplied cast exactly to size, equipped with oil holes, steady pegs, oil grooves, and backed-off at the joint, thus being quite ready to go into the hands of the engine erector.

They are produced by a very special process of our own by forcing the metal into chills while in a plastic state, and then rapidly cooled while in the chill, thus producing a dense homogeneous casting, perfectly smooth on the surface, and absolutely free from blow holes.

rranged that the materiai is susceptible to forging, rolling, and drawing, or it may be arranged hat the greatest hardness, with corresponding smaller extension, can be produced. The following able gives a summary in which the properties of 'Vickers' Duralumin' vary by such modifica- ions in the composition and treatment.

Description of the Alloy.	Specific Gravity.	Yield Point. Tons per sq. in.	Max. Stress. Tons per sq. in.	Elongation. Per cent.	Contraction.	Brinell Hardness.
H	2·77	12·06	22·25	23	34	98
681d	2·84	16·5	29·20	18	26	125

These valves are for soft rolled plates of 7 mm. thickness.

'Vickers' Duralumin' is supplied in sheets, bars, wires, strips, forgings, stampings, various ections and tubes.

Wolframinium.

Wolframinium is an alloy of tungsten, copper and aluminium. Its specific gravity (2·74) about the same as pure aluminium; its tensile strength cast in sand 10 tons per square inch, chills 12 to 13 tons per square inch, forged 15 tons per square inch, rolled or drawn 16 to 20 ons per square inch. Its elongation is 3 to 5 per cent. when hard, but 10 to 20 per cent. when roperly annealed. It can be worked as easily as copper, can be forged, rolled, and drawn either ot or cold, takes a high polish and does not tarnish.

Romanium.

Romanium is an alloy of tungsten, nickel and aluminium. Its specific gravity (2·75) is a ittle higher than that of pure aluminium, its melting point about the same, its tensile strength qual to that of Wolframinium, but it is much harder and is also of greater elasticity. It can e worked either hot or cold, forged, rolled, drawn, stamped, etc. etc. It is specially recommended for large castings, large plates and angle bars for shipbuilding and machinery.

BEARING METALS.*

The requisite properties of good bearing metals are hardness, to resist wear; strength, bear compression; and plasticity, to allow of ready adjustment of the supported body on ie bearing.

Two types of bearing metal are known:—

(*a*) Bearing metals in which the hard constituents of the alloy are distributed indiscriminately throughout a soft matrix.

(*b*) Bearing metals of spongy character; the network of the sponge being moderately hard nd tough, the meshwork being soft and plastic.

These types can be grouped according to composition as follows:—

(i) Brasses and bronzes containing compounds of copper with tin, phosphorus, etc.

(ii) Bronzes containing appreciable quantities of lead.

(iii) Alloys having a tin base and containing compounds of tin with antimony, copper, etc.

(iv) Alloys having a lead base and containing compounds of tin with antimony, etc.

(v) General alloys possessed of the characteristics required of a bearing metal.

Of the above, types (i) and (ii) have been considered under the heading of 'Brass' and 'Bronze' .v.), types (iii) and (iv) are known as 'white' metals, while the majority of the alloys of type) can be termed 'white metals.' Of types (iii), (iv) and (v) it has been observed that metals hose atomic weight divided by their specific gravity gives a high number are good anti-friction etals, while the reverse is the case for metals which have a low quotient. Hence the use of ad and antimony for bearing alloys. In using white metal for bearings the best practice is to se the bearings wholly of white metal, discarding the cast-iron shells and using up the old bear- igs with the addition of a small further quantity of the more volatile constituents. White etal must be melted in a clean vessel and at as low a temperature as possible. Dross and scum the metal tends to rapid heating in service. For the metals to be properly alloyed the high

* See also Bearing Pressures, page 1039.

as well as the low melting points of these must be reached, but care must be taken not to ove heat the alloy. For a thorough alloying a temperature of about 500° C. (930° F.) and less ha been found to be sufficient. The molten metal should be stirred with a stick of pine, and a lay of charcoal always kept on the surface to prevent oxidation. The rate of cooling affects th size of the crystals and also the wearing quality. As a general rule cooling too slowly and pourin too cold produces a coarse crystal formation which is liable to heat quickly in use. In the cas of the tin-antimony alloys it has been found that the best size for the tin-antimony compoun cubes is 0·25 mm. edge. Pouring too hot on the other hand results in a soft metal. The she should be heated to a temperature of 100° C. to 150° C. (212° F. to 300° F.) before pouring th metal into it, as this not only prevents blow-holes, but reduces the tendency of the lining shrinkin away from the shell. The bearing should not be disturbed while the lining is solidifying, sinc vibration tends to enlarge the crystals and produce brittleness. The matrix of the lining shou be just stiff enough to support the crystals, and the latter should be as numerous as is consisten with these, lying clear of each other and thereby causing brittleness. A Brinell hardness o 23·5 for an alloy with a lead base and 30 for a tin base has been found to give excellent result

ALLOYS HAVING A TIN BASE.

Tin-Antimony Alloys.

These alloys, which are of type (*a*) above, are the basis of Britannia metal. The followin table indicates the uses of certain of these alloys.

Tin.	Antimony.	Use of Alloy.
86	14	For seats of stop-cocks.
80	20	For plugs of stop-cocks.
79	21	Metal for bearings.
67	33	Very hard alloy, which forms the extreme limit of the ordinary tin-antimony alloys (*Hiorns*).

Babbitt, Genuine.

This alloy, whose composition is as follows,

Tin, 83·3 ; Antimony, 11·1 ; Copper, 5·6 ;

is used on important bearings under heavy loads, such as crank-shaft, crank-pin and cross-hea pin journals. Closely similar alloys are employed for the axleboxes of the leading railways the world. Several of the French railways, however, use the following alloy, which is low in tin.

Tin, 67 ; Antimony, 22 to 11 ; Copper, 11 to 22.

Babbitt Metal, General.

In cast-iron boxes, for light work: 50 parts tin, 5 parts antimony, 1 part copper ; for heav work : 46 parts tin, 8 parts antimony, 4 parts copper. In brass boxes: 64 parts copper, 8 par tin, 1 part zinc. The bearing to be lined with the metal is first tinned with the Babbitt met mixed with twice its weight of tin.

Babbitt Metal, Plastic Metal, and Phosphor Bronze.

(*The Delta Metal Co. Ltd.*)

These metals are supplied by the Delta Metal Co. Ltd., in various grades ; phosphor bronze i supplied in three qualities, A, B and C. The A quality is a hard bearing metal specially suitabl for worm-wheels, bushes, crank pins, bearings, etc. ; B quality phosphor bronze is a bearin metal more suitable for general purposes, whilst the C grade is adapted for large pinions, worms, etc The Company also supply various grades of Babbit, plastic, and other lining metals, for variou speeds and pressures.

Admiralty White Metal.

Tin, 86·0 ; Antimony, 8·5 ; Copper, 5·5.

ALLOYS HAVING A LEAD BASE.

Lead-Antimony Alloys.

These alloys should not contain more than 18 per cent. of antimony if they are not to be brittle. Such as do contain upwards of 18 per cent. of antimony must be given suitable support. The following table indicates the increase of Brinell hardness numbers of these alloys with increase of antimony.

Antimony. Per cent.	Brinell Hardness Number. 10 mm. 100 kilos.
2	9 approx.
5	12 ,,
10	16 ,,
15	17 ,,
20	21 ,,

The 25 per cent. antimony alloy is used by the Eastern Railroad of France as a lining for cross head slides, rod brasses and axle-bearings.

'Magnolia.'

Lead, 80; Antimony, 14; Tin, 6.
Lead, 79; Antimony, 20; Tin, Copper, etc., 1.

Other Ternary Alloys having a Lead Base.

Following is a list of ternary alloys of lead, tin and antimony, showing the mechanical properties of the same:—

No.	Lead (by difference).	Tin.	Antimony.	Yield Point. Tons per sq. in.	Tenacity. Tons per sq. in.	Elongation per cent. $l = 4\sqrt{a}$	Compression. Load in Tons required to compress to Half Length.	Brinell Hardness Number. 10 mm. ball, 200 kilos.

20*	65·0	10·0	25·0	Broken in machining			8·3 *	33·6
21	64·2	5·9	29·9	3·75	5·62	1·0	6·5 *	28·8

N.O.—Not observed. C.—Cracks in compression test-piece.
S.C.—Slight cracks in compression test-piece. * Failed without compression to half length.

The results contained in this table are considered sufficient to merit the following conclusions (1) that the effect of the presence of the tin-antimony compound in these alloys is such as to render the same brittle and weak; (2) that the general mechanical properties of the lead-tin-antimony alloys containing less than about 15 per cent. of tin are improved by the addition of antimony in quantities not exceeding about 10 per cent.

Hughes recommends the following alloy for metallic packings :—

Lead, 70 ; Antimony, 13 ; Tin, 17;

while the following alloys are used as lining by the Eastern Railroad of France :—

	Lead.	Antimony.	Tin.
1	70	20	10
2	80	8	12

1. For eccentric straps and bronze slide valves.
2. Special alloys for metallic rod packing.

Ternary alloys of lead, antimony and copper are also in use. These alloys should contain from 15 to 25 per cent. of antimony and not more than 10 per cent. of copper.

Anti-Friction Alloys.

Delta Anti-Friction Alloys.

(The Delta Metal Co. Ltd.)

Delta White Antifriction Metals, Nos. 1X and IXa, are used for lining bearings, bushes, etc., and are particularly suitable for heavy bearings such as those of marine engines, for railway trucks, dynamos, etc., as they do not wear, heat, or cut the journals ; they are also cheap.

The application of the metals presents no difficulties whatever; the parts required to be lined should be thoroughly cleaned, and when the metal is melted (which may be done in a ladle, over a slow fire, taking care not to overheat it) it is applied in the usual way. The melting point is about 450°C.

Fry's Anti-Friction Alloys.

(Fry's Metal Foundries, Ltd.)

These anti-friction alloys cover the whole range of white metals employed in engineering practice ; commencing with lead-free alloys of high tin content with sufficient antimony and copper to provide necessary hardness and wearing qualities combined with great toughness (as in the O1 brand) which are used for special service, as in the big end bearings of engines for aircraft or high-powered cars, and ending with the finest quality of lead-base alloys of the Magnolia class.

The series includes bearing metals suitable for every class of service, heavy and light loads, high speeds and slow-running machinery, and plastic metal for emergency and special services. The high-tin alloys are self-tinning. All but the first alloy in the series have a structure consisting of a matrix of tough and durable alloy with cuboid antimony-tin crystals regularly embedded throughout. The first is a tin-antimony solid solution with crystals of copper-tin and copper-antimony constituents interspersed in dendritic or needle-shaped formation. The constituent of dendritic crystal form is actually present in all well-balanced alloys of this character, adding greatly to their toughness and durability, and also serving to ensure the even distribution of the cuboid antimony-tin constituent. Finally, hard and highly resistant zinc-tin rock crusher bearing metal of great endurance can be furnished.

The following table shows a selection of bearing metals for particular purposes and for design work :

	Constituents, per cent. A = Tin ; B = Antimony ; C = Copper ; D = Lead.				Tensile Test.		Brinell Hardness. Number. 10 mm. Ball 500 Kilos.	Compression Test. Tons per sq. in.

Richards' Plastic White Metal.

The chief qualities and advantages of this metal are durability, adhesiveness, self-tinning and antifrictional properties, minimum of contraction and linear expansion when passing from the plastic to the solid state.

This alloy can be applied to many kinds of metals, including gun-metal, steel, wrought and cast iron, also aluminium, by its own self-adhesiveness, and when properly applied no abrasive force will remove it, thus dispensing with the trouble and expense of recessing or pegging, an important matter when time for repairs is limited.

It can also be used for lining up worn parts of machinery in addition to bearings. It has a low coefficient of friction, thus saving very considerably on the cost of lubrication.

Even should lubrication be neglected for a period, the metal will not run out of the bearing, but being of a plastic character, when it becomes over-heated, will simply deposit from one place to another, and thus solidify itself when in contact with lower temperatures surrounding the body of the bearing. By this means it also prevents the possibility of cutting the crankshaft or other parts that may come in contact with it.

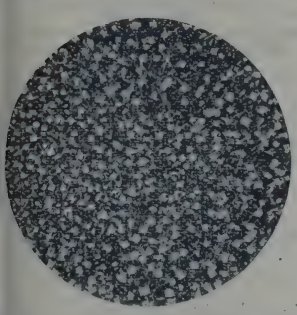

Fig. 17.—Micrograph of Richards' Plastic Metal (Magnified 50 Diameters).

The metal being self-tinning, no tinman's solder or tin is required to first coat the parts to be relined.

Its specific gravity being as much as 33 per cent. lighter than a lead basis alloy, less weight of metal is necessary for lining.

The metal itself has a particularly fine structure, which is attained by a special process of alloying. This structure is not affected by reheating, during its period of use, or when remelting, unless an exceedingly high temperature is attained. It can therefore be used over and over again.

This plastic metal has been extensively used for motor transport engines, aero engines, stationary engines, and pump work, for lining up bearing shells, and for die casting. It is particularly suitable for this last purpose. In order to produce solid die castings it is essential that the metal should be cast under pressure at a low temperature so as to preclude, by the retention of the metal as a solid rather than a fluid, the possibility of air holes and segregation of the alloy.

Richards' Plastic White Metal lends itself to these conditions. After prolonged trials it has been found that bearings made by this process are eminently suited to the onerous duties to which aircraft bearings are subjected.

The manufacturers of this alloy and bearings are Messrs. J. H. Richards & Co. Ltd., Cato Street North, Saltley, Birmingham.

Hoyt's Metals.

Hoyt's Standard Babbitt or Anti-friction Metals are made in eight qualities, this range being sufficient to meet the conditions in every class of machinery. The two highest qualities are 'Number Eleven' Alloy and the I.C.E. ('Internal Combustion Engine') Brand.

'Number Eleven' Alloy was, during the war, largely used for the bearings of aircraft engines, nearly 800 tons being supplied in 1918 for this purpose alone. This metal is also stated to give excellent results in the bearings of automobile engines, marine petrol and oil engines, steam turbines, marine steam engines, Diesel engines, etc. Its specific gravity is 7·34, the weight per cubic inch being ·268 lb. Approximately 100 lbs. of 'Number Eleven' Alloy will go as far as 113 lbs. of a high-grade metal of, say, 8·5 specific gravity.

'Number Eleven' Alloy is in use by the British Admiralty for certain important work. It is of higher quality than the Air Ministry's *Specification L.* 9 for Anti-friction Metal for Aviation engines.

The I.C.E. ('Internal Combustion Engine') Brand has been used extensively for many years by British and Continental motor-car manufacturers. It was used during the war by the British Army Mechanical Transport, the I.C.E. Brand being adopted as standard after many tests. The metal is largely used for high-speed steam engines, locomotives, steam pumps, marine engines, air compressors, etc.

Miscellaneous Metals for Bearings and Engine Parts.

The following special mixtures are stated to be satisfactory for the duty mentioned:—

For Lining.	Tin.	Lead.	Zinc.	Antimony.	Copper.	Bismuth.
Dynamos—high speed	88	—	—	8	3·5	0·5
Marine engines	77	17	—	3	3	—
Eccentrics	5	78	—	15	2	0·25
Submerged bearings	40	48	—	10	2	—
Main bearings	34	44	—	16	6	—
Slides, thrusts	63	—	30	2·5	2·5	—

ZINC-TIN ALLOYS.

Zinc and tin form a series of eutectiferous alloys, some of which are of value as bearing metals. The alloys, in common with all bearing metals, are very susceptible to differences in casting

emperature, as may be gathered from the following table, which gives in detail the effect of arying the temperature of casting an alloy of 70 per cent. of zinc and 30 per cent. of tin :—

Casting Temperature.	Maximum Stress.	Elongation. Per cent.	Stress to compress to half length.
525° C.	5·09	3·0	7·7
500° C.	6·17	3·0	13·6
475° C.	6·56	8·0	15·4
450° C.	7·37	17·5	14·8
425° C.	7·37	35·5	15·0
400° C.	7·24	20·0	15·8

The above figures are for chill castings.

The alloys of zinc and tin containing from 25 to 75 per cent. of zinc possess, when in the chill ast condition, tenacities varying from 6·0 to 6·5 tons per square inch, percentage elongations arying from 30 to 45, and are compressible to half-length under stresses (calculated on the original reas of the test-pieces) varying from 13 to 17 tons per square inch. The eutectic melts at about 00° C. and contains 16 atomic per cent. of zinc.

In order that these alloys may approximate more closely to type A (*q.v.*) bearing metal, the nc-tin series containing no relatively hard constituent, copper and antimony are frequently added. he addition of one or both of these constituents results in the formation of a bearing metal in hich the hard compounds of antimony and zinc, etc., are indiscriminately distributed throughout ie eutectiferous matrix. The following are analyses of certain alloys of this type :—

Zinc.	Tin.	Copper.	Antimony.	Use of Alloy.
80	14·5	5·5	—	Fenton's alloy for locomotive axle-boxes.
69	26·0	5·0	—	Propeller bush.
88	2·0	8·0	2·0	Bearing metal for general use.

In this connection it may be noted that ternary alloys generally are far preferable to complicated ixtures and usually fulfil all the requirements of good bearing metals.

A French report on new anti-friction metals includes trials of alloys consisting chiefly of uminium, cadmium, magnesium, and especially of zinc. Such alloys were designed to reduce far as possible the use of copper, tin, lead, and antimony, and the most satisfactory results e stated to have been given by a compound of 63·3 per cent. of zinc, 21·3 per cent. of tin, per cent. of lead, and 3·3 per cent. of copper.

FUSIBLE METALS.

With the following combinations of metals, which form 'eutectiferous' alloys, it is possible to epare an alloy having a melting point lower than that of any member of the series.

Series.	Alloy with Lowest Melting Point (Eutectic).	Melting Point.
Bismuth-lead	57·4 per cent. Bismuth	124·5° C.
Bismuth-tin	56·7 ,, ,,	137° C.
Bismuth-cadmium	60 ,, ,,	146° C.
Cadmium-tin	52 ,, Cadmium	177° C.
Lead-tin	38·5 ,, Lead	180° C.
Cadmium-lead	17·4 ,, Cadmium	247·3° C.

By the addition of one or both of the residual metals to any of the above combinations, systems of ternary and quaternary alloys, having individual members with melting points lower than those of all other members of these systems and less than those of the eutectics given above, may be obtained. These ternary and quaternary alloys are the true 'fusible metals.'

The alloys of lead, tin and bismuth are of value for the following purposes :—

(i) The manufacture of casts of delicate objects that would be damaged if subjected to high temperatures. The following alloys are recommended for this purpose :—

Bismuth	59·2	50·0	50·0	50·0
Lead	27·3	31·2	30·0	25·0
Tin	13·5	18·8	20·0	25·0

These alloys expand considerably on cooling and are valuable also for the taking of impressions from dies, medals, etc.

(ii) Fusion pyrometers. Parkes and Martin recommend the following fusible metals as pyrometers for the tempering of steel tools. The article to be treated is placed on a plate of the alloy, which is heated till it melts. The tool, being then in the required condition, is quenched in water.

TABLE OF MELTING POINT OF BISMUTH-LEAD-TIN ALLOYS.

Bismuth.	Lead.	Tin.	Melting Pt.	Bismuth.	Lead.	Tin.	Melting Pt.
50·0	31·2	18·8	94° C.	16·6	33·2	50·2	158° C.
47·0	35·5	17·7	98° C.	16·0	36·0	48·0	155° C.
42·1	42·1	15·8	108° C.	15·3	38·8	45·9	154° C.
40·0	40·0	20·0	113° C.	14·8	40·2	45·0	153° C.
36·5	36·5	27·0	117° C.	14·0	43·0	43·0	154° C.
33·3	33·3	33·3	123° C.	13·7	44·8	41·5	160° C.
30·8	38·4	30·8	130° C.	13·3	46·6	40·1	165° C.
28·5	43·0	28·5	132° C.	12·8	49·0	38·2	172° C.
25·0	50·0	25·0	149° C.	12·5	50·0	37·5	178° C.
23·5	47·0	29·5	151° C.	11·7	46·8	41·5	167° C.
22·2	44·4	33·4	143° C.	11·4	45·6	43·0	165° C.
21·0	42·0	57·0	143° C.	11·2	44·4	44·4	160° C.
20·0	40·0	40·0	145° C.	10·8	43·2	46·0	159° C.
19·0	38·0	43·0	148° C.	10·5	42·0	47·5	160° C.
18·1	36·2	45·7	151° C.	10·2	41·0	49·5	161° C.
17·3	34·6	48·1	155° C.	10·0	40·0	50·0	162° C.

(iii) Soft solders. For the union of metal to glass, e.g. in the manufacture of paraffin lamps, the following alloy has been suggested :—

Lead, 40·0; Bismuth, 33·4; Tin, 26·6.

(iv) Fusible plugs.

The above alloys are nearly all of a brittle character. For the manufacture of ductile fusible alloys the use of cadmium in place of bismuth is recommended.

The following table includes the best known of the other fusible metals :—

Alloy.	Cadmium.	Lead.	Tin.	Bismuth.	Melting Pt.
Fusible alloy . .	12·5	25·0	12·5	50·0	55·5° C.
Lipowitz's alloy .	10·0	26·6	13·3	50·0	60–68° C.
Woods' alloy . .	15·4	30·8	15·4	38·4	71° C.
Fusible alloy . .	34·5	27·5	10	27·5	75° C.

,, ,, . .	11·1	—	33·3	55·6	95° C.
,, ,, . .	25	—	25	50	95° C.

Spence's Metal.

This compound is obtained by melting the three sulphides of iron, zinc and lead with sulphur. he product is a dark grey mass of great tenacity, small power of conducting heat, a specific ravity of 3·4, a melting point of 160° C. In congealing it expands like bismuth and type metal, nd resists in a remarkable degree the action of atmospheric influences, alkalies and acids, even of quaregia, its surface scarcely being affected after having been exposed to the action of the latter r four weeks. Its property of expanding in congealing, and therefore filling completely all epressions of the mould, makes it particularly available for castings. If the compound is poured n a plate on which the impression of the hand has been made, the cast will show all the lines nd the pores of the palm.

The metal has been used for jointing gas and water pipes.

For further particulars see Patent Specification No. 2706, 1879.

Non-Magnetic Alloys.

These alloys are used as substitutes for steel wherever it is employed in the works of watches. he composition of the alloys varies from 45 to 75 parts of palladium, 15 to 30 parts of copper, 0 to 25 parts of silver, with sometimes the addition of small proportions of iron, steel, nickel, gold nd platinum. These alloys are claimed to be unoxidisable in moist air, to preserve their elasticity ndefinitely, not to vary sensibly with changes of temperature, and to remain uninfluenced by roximity to dynamos.

Another non-magnetic alloy, recently brought out by Messrs. Ostermann & Lacroix, of Geneva, Switzerland, is made of from 30 to 40 parts of gold, 30 to 40 parts of palladium, 0·1 to 5 parts of

rhodium, 10 to 20 parts of copper, 0·1 to 5 parts of manganese, and the same proportions of silver and platinum. The copper and manganese are first mixed, after which the other articles are added; or all the metals may be put into a crucible at the same time, the manganese being used for the bottom layer.

A non-magnetic variety of 'Bull's Metal' is manufactured and sold as No. III. and is being adopted for funnels and other erections of warships where the material must possess the mechanical properties of steel without its magnetic influence.

The Delta Metal Co. Ltd., supply under their "Delta" Brand non-magnetic metals (bronze and brass) to meet special requirements.

SOLDERS AND SOLDERING.

The following notes are published with the kind permission of the Editor of 'The Metal ndustry.' (See 'The Metal Industry,' vol. 9, No. 4.)

Points to be Observed for Successful Soldering.

Attention should be paid to the following points if success is to be attained in soldering or razing :—

1. In the preparation of the solder, uniformity of composition should be aimed at. Readily olatile or oxidisable constituents should be retained.

2. In the choice of the solder, consideration should be taken of the fusibility of the solder. The elting point of the solder should be less than that of the metal to be soldered. It should be oted, however, that the more nearly the melting point of the solder approaches that of the etal to be soldered the better is the union obtained, although the more difficult is the operation f soldering. It should be considered whether the solder will mingle perfectly with the surfaces o be united. One having mechanical and physical properties as nearly as possible approximating o those of the metals to be united should be used. One whose mechanical and physical roperties will not be subsequently modified by any treatment—thermal or otherwise—should be mployed.

3. In the operation of soldering, thorough mechanical and chemical cleanliness of the surfaces o be united must be obtained, e.g. by scraping, filing, grinding, etc., and by dipping in suitable hemical reagents. A source of heat both smokeless and sufficiently hot to raise the temperature f the sections to be united above the melting point of the solder is necessary. A suitable flux ust be used.

Fluxes.

Fluxes are used to protect the surfaces of the metal to be united from the oxidising action of he atmosphere during the process of heating. The presence of any non-metallic materials, such s oxides or carbonates, on the surfaces to be joined, effectually prohibits perfect union. As the rocess of heating a metal in the air always leads to the formation of a film of oxide on its surface leans must be employed to protect the surface. Use is made of readily fusible salts and of oils hat are non-volatile at the temperature of soldering for this purpose. For hard-soldering borax practically the only flux employed. It is applied as a paste with a brush to the surfaces of nall articles, and as a powder to those of larger articles. For soft-soldering a variety of naterials is used, the following list giving the most important of these, together with their uses.

(i) Zinc chloride is used for the soldering of sheet metal, copper alloys and bright iron. It is oisonous and corrosive, and is on these accounts unsuited (*a*) for the soldering of tins destined o contain food, and (*b*) for the production of delicate work, e.g. electric fuses.

Zinc Chloride Solution.

Kill 2 quarts hydrochloric acid with all the zinc it will take up. Add a quart of water or add art until zinc is fairly dissolved. A quart of glycerine which has been mixed with a quart f alcohol is then added to the solution.

This fluid is used for all kinds of soldering, especially with greasy and dirty connections and on. It is claimed that glycerine prevents rust, which plays havoc with other soldering solutions ntaining hydrochloric acid. (*Street Railway Journal.*)

Zinc Chloride Paste.

1 lb. vaseline or petrolatum ; 1 oz. (fluid) saturated solution of chloride of zinc.

The use of petrolatum instead of vaseline is recommended. While they are identical in composition, the name 'vaseline' is registered as a trade-mark, and commands a higher price on this account. Petrolatum is much cheaper. The chloride of zinc solution is made by dissolving as much zinc in strong muriatic acid as it will take up. An excess of zinc should be present, and all the acid neutralised. This will form a thick, oily solution. The petrolatum and chloride of zinc are mixed and thoroughly incorporated by means of a mortar and pestle or by vigorous stirring. The advantage of this soldering paste lies in the fact that it does not spatter and is not corrosive.

(ii) Ammonium chloride is used as a flux when soldering copper and iron.

(iii) Ammonium phosphate is used when treating with tin, zinc, copper and brass ware. It is non-corrosive and non-poisonous, but is somewhat refractory.

(iv) Hydrochloric acid is employed when dealing with zinc and zinc-coated ware.

(v) Lactic acid is useful in connection with copper and its alloys, but has the disadvantage of producing a tarnish on the surfaces adjacent to the soldered surfaces.

(vi) Venice turpentine and Gallipoli oil are used (separately) when soldering pewter or britannia metal.

(vii) Russian tallow is employed when soldering heavy lead work.

(viii) Palm oil is employed in the treatment of light lead work.

(ix) Resin is an advantageous flux when subsequent corrosion is likely to be deleterious. It is used on soft alloys and tinware.

Hard Solders.

The hard solders may be divided into two groups, each of which will be considered separately in succeeding paragraphs—brazing or 'spelter' solders and silver solders.

Brazing or 'Spelter' Solders.

The basis of the brazing or 'spelter' solders ('spelters' they are commonly called) is brass. As the percentage of zinc is increased in the brasses so does their utility as solders for the more readily fusible metals and alloys increase. There is, however, a limit beyond which the addition of zinc to these alloys serves no useful purpose, owing to the fact that the resulting alloys are, on account of their brittleness and weakness, of no practical value. This limiting value is at about 45 per cent. of zinc. The particular alloy which is in most general use contains 50 per cent. of zinc and melts at about 875° C. (1607° F.). It is employed in brazing general brass work, which is possessed of melting points varying from about 890° C. (1634° F.) to about, 1000° C. (1832° F.). For brazing metals, etc., having higher melting points than the above brasses containing a less percentage of zinc are used. Thus, for the soldering of general ironwork the brass containing 35 per cent. of zinc is used, while for the brazing of copper and light ironwork that having 40 per cent. of zinc is employed. The most malleable solder contains some 30 per cent. of zinc, but its refractory nature somewhat subtracts from its value.

For certain purposes, the above alloys, owing to their yellow colour, are prohibited. Occasionally—e.g. in the brazing of nickel silver and iron—whiter alloys are required. For this purpose alloys containing nickel are employed, of which the following are examples :—

Copper per cent.	Zinc per cent.	Nickel per cent.
37·50	50·00	12·50
35·00	57·00	8·00

Other white solders, for use in the brazing of brass and more fusible than 'spelters,' contain a percentage of tin. Two such solders are given below :—

Copper per cent.	Zinc per cent.	Tin per cent.
43·34	6·66	50·00
57·50	25·00	17·50

The British Engineering Standards Association has issued a Specification (No. 263—1926) covering two grades of brazing solder. The copper contents for the two grades range from 53 to 55 per cent. and from 49 to 51 per cent. respectively, maximum limits being specified for the tin, antimony, arsenic, bismuth, iron and lead permitted in the alloy. A table is included as an appendix to the specification giving a range of grain sizes of granular solder to which it is recommended that the material be ordered.

Silver Solders.

Silver solders are employed for soldering gold, silver, copper, iron, and their alloys, the flux generally used being borax, though with very hard solders—i.e. solders having high melting points—powdered glass is sometimes of value.

Such as are suitable for general soldering and brazing, and containing an excess of base metal, are tabulated below :—

Copper per cent.	Silver per cent.	Zinc per cent.	Uses.
90—95	10—5	—	Solder for thin sheets of mild steel.
55·0	45·0	—	Alloy for instrument-makers ; tough and fluid.
50·0	30·0	20·0	Solder for small brass work.
46·0	38·5	15·5	Solder for bronze and nickel silver.
43·0	9·0	48·0	Solder for general work on copper alloys.

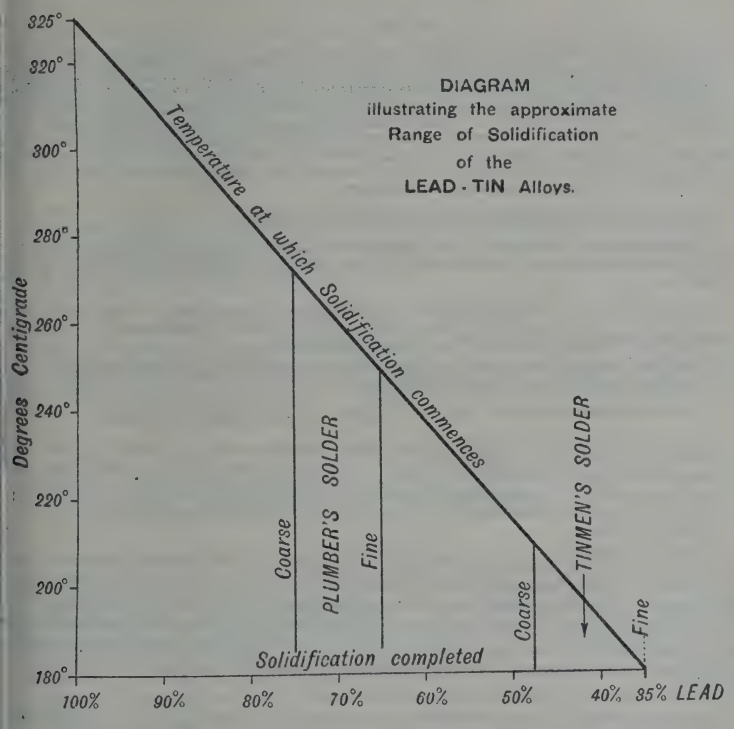
Tin-Lead Solders.

Tin and lead form a series of alloys, of which only those containing upwards of 35 per cent. of lead are employed as solders. These alloys may be divided into two classes, those that solidify at practically one definite temperature and those which are pasty over a considerable range of temperature before they become compeltely solid. The former are used as tinmen's solders, the latter as plumbers' solders, their value to each of these craftsmen being dependent on the properties associated with their solidification already mentioned. The diagram on page 2737 indicates the ranges of composition of the two types of solder already mentioned.

It will be seen that fine tinmen's solder solidifies at a definite temperature of 180° C. (356° F.) while coarse tinmen's solder commences to solidify at about 209° C. (408° F.), passes through a

sty stage, and finally completely solidifies at 180° C. (356° F.). Soft solder is the name given the alloy containing 50 per cent. of lead, whilst the fine plumbers' solder, used in making 'iped' joints, which commences to solidify at about 250° C. (482° F.), contains 66·6 per cent. lead. A solder frequently used for the union of tinplate contains about 90·0 per cent. of lead, id hence has a very marked pasty range of temperature.

The appearance of the tin-lead solders affords some idea as to their value. The surface of ood solder should be smooth and even and rectangular castings of the same should have a stinct furrow along the centre of their upper surface. The presence of zinc, though only traces this metal be present, causes the free surface of the solder to become minutely crystalline.



ismuth, copper, and silver do not affect the surface condition of solders when present in uantities varying from 0·2 per cent. in the case of the last metal to 1·0 per cent. in the case of ie first, while antimony up to 2·0 per cent. improves, rather than otherwise, the surface ondition. The presence of any of these elements leads to a reduction of the melting point of ie solder.

To Prevent Solder Sticking to Work.

To prevent hot solder sticking to work, mix common whiting or cold-water paint with wood lcohol, and paint the part that is to be protected. The hot solder will not stick, even if the iece is held in the melted alloy. Water will do as well as alcohol to mix the paint; but alcohol the most convenient, inasmuch as it can be used without waiting for the paint to dry. If ater is used the paint must be thoroughly dry, as otherwise the moisture will cause the solder fly.

Bismuth Solders.

These solders are alloys of bismuth, tin and lead, and are in general more fusible than the tin-lead solders. The useful alloys contain from 20 per cent. to 65 per cent. of lead, from 12 per cent. to 55 per cent. of tin, and from 12 per cent. to 55 per cent. of bismuth. The alloys containing the higher percentages of bismuth are the most fusible of these solders, which are employed for general pewtering. The solder containing about 50 per cent. of bismuth and 20 per cent. of tin has the lowest melting point of the series, its value being 96° C. (205° F.).

Aluminium Soldering.

The only process that can be recommended for the uniting of aluminium when the union is to be possessed of strength and durability is welding (see p. 2761). In certain instances the soldering of aluminium to itself or to other metals may, however, be resorted to. The process of soldering is considerably cheaper than is that of welding, and this, of itself, is worthy of consideration. The soldering of aluminium, however, presents numerous disadvantages owing (i) to the ready oxidation of aluminium and the difficulty of removing the oxide formed when the metal is heated, and (ii) to the rapid disintegration under the influence of moisture of soldered joints owing to the electropositive nature of aluminium with respect to those metals that may be usefully employed in the manufacture of solders.

The aluminium solders may be divided into four main groups.

1. Alloys having an aluminium-zinc base and containing varying proportions of copper. These alloys contain from 50 per cent. to 95 per cent. of zinc and from 5 per cent. to 30 per cent. of copper.

2. Alloys having a zinc-tin base and containing small proportions of such elements as aluminium (up to 12·5 per cent.), copper (up to 2·5 per cent.), phosphorus (in traces), etc. These alloys contain from 30 per cent. to 80 per cent of tin..

3. Alloys of cadmium and zinc or possessed of a cadmium-zinc base. The cadmium content n these alloys rarely, if ever, exceeds 30 per cent.

4. Alloys that are members of none of the above well defined groups of alloys.

Of group 1 solders, those aluminium-zinc alloys, containing from 3 per cent. to 30 per cent. of aluminium, have been largely employed for general soldering. For light aluminium work, where somewhat stronger solders are required, an alloy consisting of 80 per cent. of zinc, 12 per cent. of aluminium, and 8 per cent. of copper has been found to be of value, while for heavier aluminium work a solder containing 90 per cent. of zinc, 6 per cent. of aluminium, and 4 per cent. of copper is useful.

Of group 2 solders, the most satisfactory alloy (according to the *Iron Age*) consists of 69 per cent. tin, 2·5 per cent. of 10 per cent. phosphor tin, 26 per cent. of zinc, and 2·5 per cent. of aluminium. To avoid loss of the more easily volatile of these metals, the aluminium is melted first, zinc is then added in small pieces, then tin in small pieces, and lastly the phosphor tin. No acid is used, the solder being self-fluxing, but the surfaces to be soldered or joined are covered with a thin coat of solder in the usual way, and then brought together, heated with a soldering copper (iron), blow-pipe, or torch, until the solder already upon them is melted, when pressure is applied and the joint is made. The aluminium must be heated to about 660° F. before it can be soldered.

Of group 3 solders, it can be stated that most satisfactory results have been obtained with the alloys of cadmium and zinc containing from 20 per cent. to 30 per cent. of cadmium, both as regards strength and durability.

In preparing aluminium for soldering, the parts to be united must first be scraped or filed in order that the thin skin of oxide always present on aluminium that has been exposed to the atmosphere may be completely removed.

It is scarcely necessary to state that all oil, grease, or organic matter must be completely removed from the parts to be soldered. In practically all cases solders for aluminium are best applied without a flux. Generally speaking, the process of soldering aluminium is identical with that of ordinary soft soldering. It is well, however, in the case of aluminium soldering, to heat the parts to be united until the solder will just melt upon the surfaces to be joined and then to rub the solder into the metal with a wire brush or rod, in order that intimate contact may be made between the solder and the metal to be soldered. The strength of the joint depends to a large extent on the thoroughness with which this preliminary treatment is conducted. Soldering is then continued in the usual manner.

Cold Solder (amalgam Solder).

By shaking finely-divided copper with mercury in a little dilute sulphuric acid an amalgam ın be prepared which may be used to unite joints at ordinary temperatures. The amalgam is ɔrmed into pellets, which are heated till mercury begins to exude from the surface. These ellets are wiped free from mercury and are then rubbed to a soft paste in a mortar. The ırfaces to be united are first treated with sodium amalgam (sodium 2 per cent.), the soft paste f copper amalgam being then applied. The surfaces to be joined are then tightly pressed together, ıe union being completed in about three hours.

Soldering Aluminium Bronze.

To solder aluminium bronze with ordinary soft (pewter) solder: Cleanse well the parts to be ɔined from dirt and grease. Then place the parts to be soldered in a strong solution of sulphate f copper, and place in the bath a rod of soft iron, touching the parts to be joined. After a while copper-like surface will be seen on the metal. Remove from bath, rinse quite clean, and righten the surfaces. These surfaces can then be tinned by using a fluid consisting of zinc ıssolved in hydrochloric acid in the ordinary way with common soft solder. If the surface is ot coppered an aluminium alloy must be used.

Soldering Cast Iron.

(1.)

If the part of iron to be soldered is cast iron that is hard and thin, it should be polished on n emery wheel and made clean and bright. Then dip it in potash water, after which dip it for n instant in clean water, and wash quickly with undiluted hydrochloric acid of the ordinary ɔrength; go over it with powdered resin and solder made from half tin and half lead. This must e done quickly, before the surface has time to dry.

(2)

File the surface clean, and wash as before; wipe it over with a flux made of sheet zinc dis-ɔlved in hydrochloric acid until it is surcharged, or is a saturated solution and has been diluted ith its own quantity of water; then sprinkle powdered sal ammoniac on it, and heat it on a ıarcoal fire until the sal ammoniac smokes. Dip it in melted tin, and then remove, and rap off ıe surplus tin.

CASTING AND FOUNDING.

Moulding-sand.*

(1.)

1 cubic foot sharply burnt and pulverised pure fire-clay; 60 cubic inches sugar; 2 quarts water; quart paraffin oil. No lime or charcoal must be included in the mixture. Thoroughly mix. uitable for castings of ingot iron.

(2.)

93 parts pure quartz sand; 7 parts clay free from lime; the latter acts as a cement for ıe former.

(3.)

For small castings:—Red sand, 3 parts by measure; coal dust (finely sifted), 1 part by ıeasure.

(4.)

For large castings:—Red sand, 3 parts by measure; coal dust (finely sifted), 1 part by ıeasure; chopped straw, or dried horse manure, ¼ part by measure.

The latter makes the sand light and porous, facilitating the release of the gases. As the sand ecomes impoverished by being burnt, the coal dust is renewed from time to time. If paraffin s used to damp the mould, black sand will bind and can then be dried as when red sand is used.

---

* For further information on Moulding Sands see "Sands and Crushed Rocks," by *A. B. Searle*, *Oxford University Publications*).

Moulding-sand which has partially lost its cementing power may have it restored by mixing with fresh sand.

Green, or floor sand that has ' gone dead ' (dehydrated) is frequently revived with Birmingham or Mansfield sand. Bunter sand, and also Barrow sand, have been found very good for the same purpose.

When the metal touches the clay bond the clay is undoubtedly killed, but not so the ferruginous bond, and long-life sand is generally rich in the latter.

Ferruginous bond in moulding sand is usually the cause of the production of a smooth, sound surface to the casting, particularly in the case of steel. In non-ferrous practice it is usual to ensure the smoothness of the skin by painting the surface of the mould or ' facing ' it with a layer of finer sand (facing sand) or a wash.

The washes used for painting the mould in non-ferrous work have usually either china clay or a graphitic substance as base. Graphite (plumbago) is itself used at other times. ' Scotch blacking,' which is a mixture of charcoal and graphite, is employed.

A suspension of the powder in water may be assisted by the addition of a little borax or molasses.

Cores.

For the making of ' cores ' in British foundries a ' compo ' moulding sand is made from ordinary sand such as Mansfield and broken fragments of graphite crucibles ground and mixed.

The admixture of the coarser material ensures good venting of cores; at times the sand alone is used.

Oil-bonded cores (where the oil is generally a commercial linseed, such as ' Baltic seed oil '), unlike those used in steel founding, have not met with much success in non-ferrous founding at home, but are adopted extensively in America, where a fairly coarse high-silica sand is the base. Sands from Lumberton and Howell, N.J., are so used. (*Horobin.*)

Testing Moulding Sands.

Methods of testing moulding sands are described in ' Sands and Crushed Rocks,' by A.B Searle (Oxford University Publications). A rough-and-ready test for voids and porosity consists in putting 50 c.c. of water in a glass measuring cylinder and 50 c.c. of the sand (previously passed through a 12-mesh sieve) into a graduated glass cylinder holding 100 c.c. The water is added to the sand and the cylinder with its contents is violently shaken until the water and sand are thoroughly mixed. The mixture is allowed to settle and the total volume is then measured. The reduction in volume is a measure of the volume of voids or pores in 50 c.c. of the sand.

By watching carefully, the time taken for the grains of different sizes to settle may also be noted.

To Repair Castings by Burning on.

A piece of machine-framing, the necks of rolls, or a standard which has been broken or found defective, may be repaired as follows : First cut away the defective parts down to the sound metal; build a coke fire round the part of the casting which is to be repaired until it is brought to a bright red-heat, then dust over the surface of the cut metal with powdered glass or borax. Then apply a hollow loam mould of the desired part to the casting, properly secured in position and provided with a hole for the exit of the metal. Pour very hot liquid cast iron into the mould, and allow it to flow away until the cut surface of the original metal of the casting can be felt with an iron bar to have become soft and pasty by contact with the hot liquid iron. Then stop the exit hole and allow the metal in the mould to set. If the operation has been properly performed the casting should, when struck, ring with the same sound as a single good casting, thus showing that the old and new metal are perfectly united.

Sealing up Cracks in Castings and Cementing Joints.

Cracks in the walls of pressure vessels may be patched by bolting on a plate with a thickness of sal ammoniac and iron borings beneath it. Many an external firebox sheet has been patched in this way.

A cast-iron cylinder for a hydraulic press in which the iron was so porous that, under 2,000 lb. ressure, the water ran down the outside in rivulets, has been sealed by filling the cylinder with ater containing a large quantity of sal ammoniac and letting it stand for a couple of days. At ie end of that time the cylinder was perfectly tight.

The sal ammoniac treatment has been used in railway shops for stopping cracks in bushing ylinders. In one instance an 18 × 22 in. cylinder was patched that way. It was an old cylinder iat had been bored out and a cast-iron bushing inserted. A coat of white lead was spread on ie outside of the bushing and after it was in place it was stayed to the cylinder wall by drilling oles through the wall and bushing and screwing in brass plugs. Some time later a crack running ngthwise between the plugs in the outer shell opened up for about 15 in. This was made tight y removing the piston, closing the ends of the cylinder and pouring a sal ammoniac solution rough the ports until the cylinder was full. This was allowed to stand for ten days, then ie cylinder was drained and refilled with a weak solution of muriatic acid and allowed to stand gain for about ten hours. The purpose of the muriatic-acid solution was to complete the work egun by the sal ammoniac. It was presumed that the acid would cut away the coating of ist produced by the sal ammoniac, and that the particles would gravitate toward the pressure. nd apparently this is what happened.

White lead has been used with advantage in making up threaded pipe joints and when press- g the brasses into locomotive driving boxes, placing driving pins in the wheels, etc. In the tter case the white lead acts as a lubricant while the job is being done, and later on, after it as set, it serves to cement the part pressed in. For many uses red lead is preferable to white, id next to litharge, is best for holding anything. If a threaded pipe joint is made up, say a in., with white lead, after a year's time it will still be possible to remove the fitting, but if the me fitting is made up with red lead, and it is desired to take it off after the lead has hardened, ie fitting will have to be broken unless sufficient heat can be applied to cause it to loosen from ie pipe.

There is no cementing effect when graphite and oil is used on a pipe thread. With graphite id oil on a thread a fitting can be made up tighter than would otherwise be possible. Also, ie graphite is squeezed compactly into the interstices in the joint and its very compactness olds it against blowing out under pressure, but it does not anchor the fitting. Therefore, no reater stress is necessary to remove the fitting at any time than was used to put it on.

Litharge will make a threaded pipe joint absolutely leak-proof against any kind of fluid and gainst any pressure that the pipe will stand.

(*Power*, *July* 1, 1924.)

Pattern Composition

A composition that has many advantages over wood for making small patterns can be made follows:—With hot water mix into a thick paste three parts by volume of starch, one part round glue, two parts fine resinous sawdust. The sawdust should not be added until the starch id glue have been dissolved by the water. After the ingredients are thoroughly mixed, heat ie whole to 190° F., and continue the heating until the whole becomes a hard mass, then allow cool, and remove from the receptacle. The resulting composition is a strong, hard, horn-like ibstance, that can be machined, sand-papered and varnished just as can wood. The principal lvantages of this composition over wood lie in the fact that it has no grain, and therefore turned id complicated patterns made from it do not have to be built up or glued together, and that r the same reason it is easier to turn and machine, and offers a smoother surface when finished. is also more fireproof than wood and not so readily affected by atmospheric changes.

(*American Machinist.*)

Shrinkage of Castings.

The allowance for shrinking in casting should be for each foot in length:—

	Parts of an Inch.		Parts of an Inch.
or cast-iron pipes	·125 = $\frac{1}{8}$	Brass	·17 = $\frac{3}{16}$
„ beams and girders	·1 = $\frac{1}{10}$	Lead	·31 = $\frac{5}{16}$
„ cylinders, large	·094 = $\frac{3}{32}$	Zinc	·25 = $\frac{1}{4}$
„ „ small	·06 = $\frac{1}{16}$	Copper	·17 = $\frac{3}{16}$
thick breadth	·156 = $\frac{5}{32}$	Tin	·25 = $\frac{1}{4}$
thin breadth	·156 = $\frac{5}{32}$	Bismuth	·156 = $\frac{5}{32}$

Cleaning Castings.

A large proportion of the loose sand on castings may be removed in the 'tumbling' process, but the adhering sand and scale of oxide, which soon destroy the cutting edge of the tools, are best reduced by a pickle; the following have met with general approval.

Sulphuric Acid Pickle.—Ordinary commercial sulphuric acid and water in the proportion of 1 of the former to 30 of the latter. In this case the castings are required to remain in the pickle for about 10 hours, and are then washed with hot water to remove all trace of the acid and prevent rusting.

Hydrofluoric Acid Pickle.—This acid is slower in its action and not so liable to cause corrosion as the above. The castings, however, should be first tumbled in order to remove loose sand (as the sand neutralises the solution very much more quickly than the iron) and then immersed in a mixture containing 1 of hydrofluoric acid to 15 of water. The bath should be maintained at a temperature of 120°F. by a steam coil. The castings are then washed in clean hot water and sometimes in hot water with a small proportion of lime (about 1 lb. of lime to 8 gallons of water).

The baths are best made of oak, wood pinned, with no exposed metal fastenings and well lined with asphaltum. The attendant should be furnished with wooden clogs, strong leather apron and rubber gloves to protect him from the acid.

The acid should be added *very slowly* to the *water* and well stirred in the process. Never add the water to the acid, otherwise the acid vapour will be carried all over the place.

An American factory is using high-pressure water for cleansing castings of sand and cores. A centrifugal pump, driven by a 50-h.p. motor, delivers 250 gallons per minute at a pressure of 250 lb. per sq. in., and the work is carried on in a closed chamber with glass windows. It is said that a casting which previously took a whole day to clean can be finished with the water jet in half an hour.

(See also 'Lubrication Troubles,' p. 1065.)

Dips for Castings.

Special for Electro-galvanising.—For preparing work for electro-galvanising the following can be used with advantage, but for no other solution except, perhaps, copper: Add to the dilute acid ½ lb. of sheet zinc to each 25 gals. of solution, adding additional amount occasionally as it works out.

Bright Dip for Iron.—Work that has been pickled in the ordinary way to remove sand and scale, and then dried, usually has a dull-black appearance. If the work is to be polished, the black will be removed and the colour restored in the polishing process; but if it is to be plated, or if it is to be left with parts of iron showing, the work should be run through the bright dip. This will bring it out white, improving the appearance and tending to make it take on a white deposit if it is to be nickelled. This dip is composed of :—

Hydrofluoric acid, 24 oz. Nitric acid, 10 oz. Metallic zinc, 2 oz. Water, 2 gals.

Work that is to be dipped should be strung on copper wire, and swirled around in the solution for a few seconds, rinsed in cold and then very hot water, and dried in sawdust. Articles should not be allowed to stay in the dip any time, as they would be spoiled and the solution ruined.

Satin-finish Dips.—Brass work requiring a satin finish may be dipped for a few seconds into a mixture consisting of :—

(1) Hydrofluoric acid, 1 part; Water, 3 parts;

then dried and run through the bright dip (4) to give it a lustre. If not satined enough the operation may be repeated.

(2) Hydrofluoric acid, 2 parts; Nitric acid, 1 part; Muriatic acid, ½ part; Water, 5 parts. After which the work may be rinsed, dried, and run through the bright dip (4) if necessary.

(3) Hydrofluoric acid, 2 parts; Nitric acid, 1 part; Water, 10 parts.

The following is a *bright dip* for copper, brass, bronze, or German silver :—

(4) Hydrofluoric acid, 4 quarts; Nitric acid, 3 quarts; Common salt, small handful.

Protection of Copper Castings.

The best method for protecting copper castings from oxidation in air, resulting in a coating ! verdigris, is for the casting to be done under hot water, with the metal at a very high tempera- ıre. This method, largely employed in Japan, forms a coating of red cuprous oxide, which as been known to give protection for upwards of thirty years.

Die-Casting.

ontributed by A. H. Mundey, Assoc.Inst.C.E., F.C.S., M.Inst.Met., of Fry's Metal Foundries Ltd.

Die-castings have been defined as castings produced by pumping metal into metallic dies at pressure higher than that of the atmosphere. This distinguishes them from the class of castings ıade by the permanent mould process into which the metal is simply poured, also sometimes :ferred to as die-castings and on other occasions as chill castings. There is, however, a tendency ow to make the phrase 'die-casting' embrace both the methods, and to distinguish the sections s 'gravity die-castings' and 'pressure die-casting.'

The equipment for die-casting includes a melting pot (usually of cast iron), gas-heated, placed ear the die-casting machine, for supplying the molten metal to the reservoirs of the caster.

The casting machines are of two general classes, those in which the metal is forced into the die r mould by the action of a plunger or pump, and the other in which compressed air is used for ıis purpose.

The reservoir attached to the machine is heated by gas, the pump being in direct contact ith it; the plunger is actuated, by means of a long lever, by the operator, the metal being forced om the pump chamber through a suitable nozzle into the dies. The moulds are attached to a ınged plate which swings away from the reservoir and pump nozzle, after each cast, to allow the orkmen to remove the tang and clean the metal passages.

The swinging plate is securely gripped to the reservoir at the moment of casting.

The mould is held to the swinging plate by means of a toggle joint, and varies in form and esign according to the particular castings; it is always at least a two-part mould, but usually also fitted with elaborate cores and drawbacks and mechanism for working them, which make ıe production of complex castings possible.

The dies are made in mild steel, alloy steel, and occasionally in cast iron, according to the loy and character of the work in hand. Sometimes the dies are heated, for other work they :e required to be water-cooled, so that no hard and fast line can be set in this respect.

The compressed-air type of die-casting machine consists of an air-tight cast-iron chamber ır the metal, suitably heated to keep the metal at the desired temperature. This chamber is ınnected with the die by one opening, and with the compressed-air line, by another. In the tter opening a valve is fitted with a lever for the sudden release of the air into the metal chamber. his valve also permits of a gradual decrease of the pressure on the metal after it has filled the die. his type of machine may be used on metals cast by the plunger type, but is especially suitable r metals that cannot be cast in the plunger type of machine on account of their high melting- ›int or corrosive action on the cast-iron plunger.

A die-casting die consists essentially of two parts which are brought together and maintained . perfect register by means of the usual dowel pins.

Internal threads are produced by screwed cores and externa' ones by removable screwed ıllars, whilst the holes which are usually drilled in machine-made fittings are in these cases ·rmed by means of retreating cores; the latter may be of almost any shape.

Small cores are operated by levers, large cores by a rack and pinion; they are always locked hilst the casting operation is proceeding. A vital consideration is the proper venting of the .e; the position and form of the vents can only be determined by experiment.

Great accuracy is obtainable; it is quite possible to produce castings to a limit of 0·001 inch.

Alloys used for Die Castings.

The alloys generally used are of considerable variation, according to the special purpose ıd circumstances; those of the white-brass or zinc-base group are usually approximately:

86 per cent. zinc; 7 to 10 per cent. tin; 4 to 7 per cent. copper; with 0·5 to 1·0 per cent. aluminium.

Increased tin gives greater ductility, whilst increased copper renders the alloy harder.

The tin-base alloys are (*a*) bearing alloys of all the usual grades of white anti-friction meta and (*b*) alloys specially designed to withstand the corrosive effect of chemicals in food-stuff certain gases, and even acids.

An alloy which is largely employed is :

90 per cent. tin ; 4 per cent. copper ; 6 per cent. antimony.

Of the aluminium group the most commonly used alloy is that known as No. 12, consisting of

92 per cent. aluminium ; 8 per cent. copper.

Sometimes a small quantity of magnesium is added and also frequently from 1 to 3 per cen of nickel.

The finish or skin of the casting is smooth and in a large measure satisfactory, but polishing plating, and bronzing are frequently employed, for protective as well as decorative purposes.

Shrinkage is an important consideration ; this varies greatly with the alloys used. Approx mate allowances are :

White brass or zinc base alloys . . .	0·0035
Lead base alloys	0·002
Aluminium alloys	0·007

The alloys generally used for die-castings are of relatively low melting-point and are of such constitution that they have a period of plasticity during the process of solidification. This add much to the chance of the production of sound castings.

Temperature of working is an important factor ; if too high, splashing results, with productio of long fins, oxidation, and discomfort in working. Too low temperature produces bad finis with little folds and creases on the surface, due to premature solidification.

The metals known as yellow metal—that is, high copper alloys—are cast almost exclusivel by the gravity process ; great accuracy is not obtainable for long runs, owing to the wear of th dies at the high temperature employed.

The alloys of this character usually employed are : copper, 90 to 95 per cent. ; aluminium, 1 to 5 per cent. ; also copper, 60 to 65 per cent. ; zinc, 40 to 35 per cent.

Mechanical Treatment of Metals and Alloys.

Method of Treatment.	Details of Method to be avoided.	Consequences of Details of Method of Work.
Hot working . .	1. Excess 'reduction' or rate of 'reduction.'	Cracking of metal.
	2. Deficient 'reduction' or rate of 'reduction.'	Coarse, weak metal.
	3. Excess temperature at commencement.	Weak, brittle metal and formation of fissures therein.
	4. Deficient temperature at conclusion.	Internal strain and consequent hardening. Possible 'season cracking.'
	5. Retention of scale on metal during operations.	Rough and pitted surface and possible cracking.
Cold working . .	1. Excess 'reduction' or rate of 'reduction,' without annealing.	Surface cracking and hollow drawing. Strain-hardening.
	2. Deficient 'reduction' or rate of 'reduction.'	Insufficient hardening — where hardening is expected.
	3. Unequal 'reduction' . . .	'Season cracking' or cracking during annealing.

Heat Treatment of Metals.

Method of Treatment.	Details of Method to be avoided.	Consequences of Details of Method of Work.
Annealing . .	1. At too high a temperature .	'Burning' and 'over-heating' in steel and brass. Brittleness and sponginess generally, owing to abnormal grain size.
	2. At too low a temperature . .	Insufficient structure change.
	3. For too long a period — at correct temperature.	Diffusion and aggregation of micro-constituents of metal or alloy.
	4. Careless charging in or firing of furnace.	Sudden access of heat may lead to cracking of cold metal.
	5. In an injurious atmosphere or in contact with injurious substances.	Copper is injured by reducing gases, steel by oxidising gases. Water and oil have injurious effects in many cases.
Quenching . .	1. From too high a temperature .	Cracking, warping and brittleness.
	2. From too low a temperature .	The object of the operation is defeated.
	3. Unequal	Warping.
Tempering . .	1. At too high a temperature .	Removes the effects of quenching.
	2. At too low a temperature . .	Does not remove the effects of quenching sufficiently.
	3. Unequal	Lack of uniformity and consequent failure.

SECTION XL

PART II

WELDING AND CUTTING.

(Contributed by D. Richardson, Wh. Exh., A.M.I.M.E., Capt. R.A.F.)

OXY-ACETYLENE WELDING.

The term ' autogenous welding ' is a cumbersome and loose description for the process, which s become synonymous with oxy-acetylene or gas welding, although its real meaning, ' self-)ducing,' does not fully apply. The term was chosen to describe a process in which two sections metal are melted together by means of a blowpipe in contrast with the then existing methods, which a joint was made by the addition of a different metal, as in brazing. The term ' fusion ' onsidered to be much more appropriate than ' autogenous,' and is applied to a weld worked the fluid or vapour state.

The easy control and intensity of the oxy-acetylene flame, the low cost of operation, the atively inexpensive equipment required, the range of metals which can be welded, and the equate supplies of carbide of calcium, oxygen, etc., available, are factors which have led to its ny and varied applications.

The industrial development which has taken place can also be attributed to the increased ciency of the welder and the efforts that have been made to reduce the art of welding to a re scientific basis. The uncertainty of the results, upon which opposition and criticism are ally based, can be traced to the following causes: (*a*) inefficiency of the welder; (*b*) use of ective or unsatisfactory apparatus; (*c*) use of defective or unsuitable filling materials; (*d*) of proper supervision and maintenance of the generating plant and equipment; (*e*) un-ability of the material to be welded.

It is not difficult to eliminate these causes, and a well-trained welder using good apparatus, rect filling materials, etc., can produce welded joints on mild steel, cast iron, copper, brasses, nzes, aluminium and aluminium alloys, lead, etc., with mechanical and physical properties roaching those of the base metal, and in which the strength and service of the joint are olutely reliable.

Equipment.

The apparatus required for an oxy-acetyline installation depends upon several factors, such (*a*) the class of work to be welded; (*b*) whether a portable or stationary installation meets case; (*c*) whether production or repair work, or both, are possible applications; (*d*) the ilities for installing equipment and for handling the work in prospect. In general, the aratus and accessories will comprise a generator for generating the acetylene gas, which be a fixed or portable plant—the most portable type of plant uses compressed or dissolved ylene in portable cylinders instead of a generator; chemical and mechanical purifying aratus; oxygen apparatus for the production of oxygen, or oxygen in cylinders; oxygen ulators for lowering and regulating the pressure of the gas after it leaves the cylinder, to pressure required for the blowpipe, and, in the case of dissolved acetylene, an acetylene ulator for the same purpose; hydraulic safety valve or other safety device for dealing with losive mixtures of oxygen and acetylene or air and acetylene; welding and cutting blow-s of various capacities; accessories, such as flexible tubing, goggles, welding benches, blow-support, preheating devices, tools jigs, fluxes and filling materials, carbon paste and blocks, protection, protective equipment, etc., etc.

Fig. 1 shows in diagrammatic form an elevation and plan of the general lay-out of a acetylene welding and cutting installation. The letters refer to the same details in both views.

N. 2749

For comparatively small installations, the generator, condenser, washer, water-seal, and gas-holder form a single piece of apparatus, as shown at A in fig. 2. The diagram shows at N a pilot light bracket attached to the branch tube D. An acetylene jet burner consuming about 5 litres of acetylene per hour, screwed into the bracket, forms an efficient and economical method of lighting the blowpipe. The burner should be at least 18 inches from the hydraulic safety valve and not more than 6 ft. above floor level.

An installation of the type described is known as a low pressure installation, to distinguish it from the type in which the acetylene is obtained from cylinders, known as the high pressure system.

Fig. 3 shows the equipment for the high pressure system. After passing through suitable acetylene and oxygen regulators the gases are conveyed to the blowpipe by means of flexible tubes.

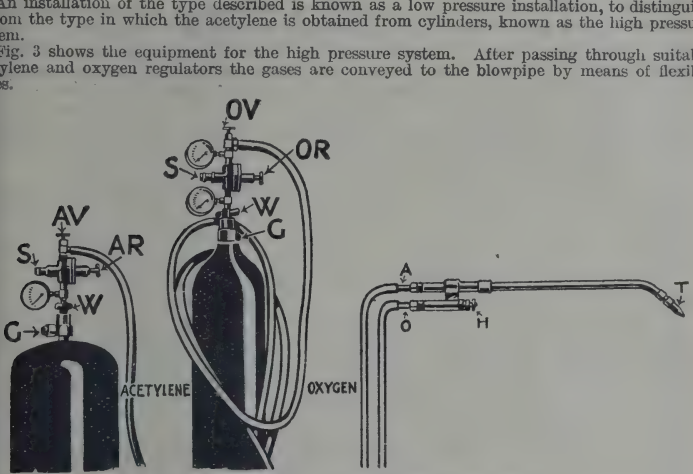

FIG. 3.—High Pressure or Dissolved Acetylene Installation.

OXYGEN SUPPLY.

The oxygen may be obtained in cylinders or may be produced on the premises. There are three methods of production, namely :—(1) chemical processes; (2) the electrolytic process; (3) the liquid air process. The older chemical processes are practically obsolete as regards oxygen for welding and cutting. Modern chemical processes are represented by the Oxygenite, Oxylithe, and Epurite processes. The Oxygenite process consists in the liberation of oxygen in a closed vessel by the self-combustion of a powder called Oxygenite, which is composed chiefly of potassium perchlorate, to which are added small quantities of powdered carbon and fullers' earth. One pound of Oxygenite will set free a little more than 5 cu. ft. of oxygen of 95–96 per cent. purity. In the Oxylithe process the chemical is brought into contact with water and the gas is liberated in a similar manner to the production of acetylene from calcium carbide. In the Epurite process the Epurite, which is a mixture of chloride of calcium, sulphate of iron, and sulphate of copper, diluted with water, produces oxygen. The main objections to chemical processes are the cost and impurity of the gas. The effect of impure oxygen in welding is to retard the welding operation, and thus increase the cost, and a tendency to produce blowholes. In cutting operations the purity of the oxygen is a most important factor, and tests have shown, for example, that with oxygen of 91 per cent. purity the cutting speed is halved when compared with oxygen of 98 per cent. purity. Simple and cheap apparatus is available for rapidly and accurately testing the purity of the gas.

The electrolytic and liquid-air processes may be used for producing oxygen on the premises. The gas can then be charged into cylinders or piped into the welding shop from large receivers into which it has been compressed, or it may be piped direct from the oxygen-producing plant. For information on 'Industrial Oxygen' reference should be made to a paper read by T. Campbell Finlayson on the subject before the Institution of Chemical Engineers, in June 1923, and the Report of the Oxygen Research Committee, Department of Scientific and Industrial Research, Sept. 1923.

Oxygen produced by the electrolytic or liquid air processes has a purity of the order 99 per cent. Unless the consumption is very large the first cost of an oxygen installation is comparatively high, and the majority of users obtain the gas in cylinders from the manufacturers. The cylinders supplied by the manufacturers for welding and cutting usually contain 100 cu. ft. of gas at a pressure of 1,800 lbs. per sq. in. (120 atmospheres). The Gas Cylinders Research Committee of the Department of Scientific and Industrial Research have made a series of recommendations for ordinary commercial cylinders used for the storage and transport of gases, including oxygen,

and are at present engaged on the standardisation of the fittings of gas cylinders.* They have also issued a Second Report dealing with the periodical heat-treatment of gas cylinders.† The Oxygen Research Committee have issued a Report mainly dealing with the storage and transport of liquefied gases, but also including a summary of the recommendations relating to compressed oxygen.‡ The British Engineering Standards Association have also formed a committee with a view to standardising cylinder valves and fittings.

In handling oxygen cylinders care must be taken against leakages, and particular care must be exercised not to oil or grease any part of the oxygen apparatus or supply line. Dust and moisture should be expelled by opening the cylinder valve before the cylinder is put into use. Repairs to cylinder valves should not be attempted by the user, and full cylinders should be handled carefully. All oxygen cylinders are fitted with valves having right-hand connections, and are generally painted black. No attempt should be made to transfer oxygen from one cylinder to another by rigging up some form of communicating tube. In the majority of cases a separate cylinder is used for each welding station or blowpipe in use. In some cases a number of oxygen cylinders are manifolded together, the gas being supplied to the shops through a system of piping. Oxygen manifolds should be able to withstand a pressure of at least 3,000 lbs. per sq. in., and each cylinder connection should be equipped with a high-pressure shut-off valve. It is extremely advisable that the necessary manifolds be purchased from a responsible manufacturer or made to specification. A cylinder valve should never be opened suddenly when the oxygen regulator is attached. In the event of the oxygen supply being restricted owing to the freezing of moisture in the cylinder valve, hot water only should be used to put it right. Leakages can be discovered by the hissing noise produced by the escaping oxygen, by the use of soap-suds spread over likely places, or by closing the valves on the blowpipe, cylinder and regulator, and noting how long the pressure holds up the gauges. Cylinders should be placed where they cannot be easily knocked over, and never near sources of heat. Spare cylinders should be safely and properly stored, care being taken not to store them near radiators, oil, grease, or combustible materials.

For estimating costs of welding, the following table will be found useful. The table gives the number of cubic feet of oxygen remaining in a 100 cu. ft. cylinder corresponding to various readings of the high-pressure gauge on the oxygen regulator. The amount of oxygen indicated by the gauge reading is more or less approximate as it depends upon the temperature of the oxygen. For practical work the deviations can be ignored, and would not affect the usefulness of the table. In general, the volume of oxygen in a cylinder is nearly proportional to its pressure, and thus, in the absence of the table, the volume of gas remaining in a cylinder can be determined by observing the gauge. A regulator provided with a pressure gauge which serves the double purpose of registering the pressure of the gas in the cylinder and indicating the amount which has been used on a welding or cutting operation, can be used.

Gauge Pressure in Atmospheres.	Cubic Feet of Oxygen in Cylinder.	Gauge Pressure in Atmospheres.	Cubic Feet of Oxygen in Cylinder.
10	8·3	70	58·4
20	16·7	80	66·7
30	25·0	90	75·0
40	33·4	100	83·4
50	41·7	110	91·7
60	50·0	120	100·0

At atmospheric pressure and temperature oxygen is rated at 12·08 cu. ft. per pound.

The idea of distributing oxygen in a liquid state and allowing it to gasify under control on the premises is being advocated, but there are many difficulties in actual practice which outweigh or eliminate the theoretical advantages claimed for this system.

Oxygen is supplied to the trade at prices which vary according to the size of the cylinder, quantity purchased, and other conditions. Cylinders are loaned, or may be purchased outright. Demurrage charges are made on hired cylinders when retained above a certain period. Oxygen cylinders are conveyed by the railway companies under strict regulations and conditions.

Acetylene Supply.

The acetylene may be obtained compressed in cylinders filled with a porous material, the pores of which hold a film of acetone in suspension, it is then known as dissolved or compressed acetylene, or may be generated on the premises. The precautions in handling acetylene cylinders are much the same as for oxygen cylinders. The gas should not be drawn off at too high a rate; in other words, the greater the demand the larger the cylinder. A recent investigation has been made to determine the percentage of acetone vapour in dissolved acetylene at varying temperatures and pressures. The figures show that the output of the flame diminishes by 1·8 per cent. for

A-L

A-L SERVICE

for all welding processes Oxy-Acetylene Electric Arc and Electric Resistance

Engineers and manufacturers are invited to make use of the Company in any matter relating to welding. A staff of experts and demonstrators in each of the three main systems is always available to discuss problems and to show what can be done under practical conditions. Speed of work, strength, and economy are the objects of all welding processes. Their adoption is daily increasing in all sorts of manufacturing and repair work. For the fullest information and enthusiastic help, write or telephone to the Company's Head Office, or to the nearest Branch.

1 per cent. of acetone vapour in the flame. The temperature of the cylinder should be kept low and the cylinder pressure should not fall too low in order to keep the percentage of acetone vapour low. For heavy continuous work two or more cylinders should be manifolded together by means of special adaptors supplied by the manufacturers. For general work cylinders containing 100 to 250 cu. ft. of gas are advisable. All acetylene cylinders used for oxy-acetylene welding are provided with valves screwed with left-hand threads. Cylinders for welding and cutting can be hired or purchased.

Before the gas is compressed into cylinders it is first purified and dried by several processes, and then compressed into solid drawn seamless steel cylinders.

The acetylene and oxygen being under high pressure, a perfectly uniform mixture of both gases can be maintained in the blowpipe and the pressure varied according to requirements. The elimination of the injector device, necessary in low-pressure blowpipes, and the hydraulic safety valve are advantages claimed for dissolved acetylene. Dissolved acetylene can be used with any type of oxy-acetylene blowpipe, but it should be recognised that the device for dealing with back-fires and flash-backs does not, as a rule, form part of the details of low-pressure blowpipes.

No demurrage charges for the use of cylinders are made on hired cylinders returned within thirty days of despatch, so that it is not necessary to purchase cylinders, although these can be supplied. Acetylene is supplied to users of purchased cylinders of 100 cu. ft. capacity and upwards at reduced prices.

The amount of acetylene in a cylinder cannot be determined, as in the case of oxygen, from the pressure gauge reading. The only accurate method of calculating the gas used from, or left in, a cylinder is by weighing before and after use. The empty and full weights are shown on a label fixed to each cylinder after charging. For calculating the volume of acetylene used the following are the equivalents:

1·1 oz. of acetylene = 1 cu. ft. (approx.)
1 lb. ,, ,, = 14·5 cu. ft. ,,

By means of an acetylene generator acetylene is produced by the interaction of calcium carbide and water. There are three general types of acetylene generators which may be classed under the heads of water to carbide type, carbide to water type, and the dipping or displacement type. They can also be classified as low-pressure and pressure generators. Briefly, low-pressure generators deliver acetylene to the blowpipe at a pressure of about 8 ins. water pressure (0·036 lb. per sq. in.), whilst pressure generators deliver the gas up to a maximum fixed by regulations at 250 ins. water pressure (9 lbs. per sq. in.). The latter are not in general use.

The design and layout of a generating plant must be such that the acetylene reaches the blowpipe in a good condition, in sufficient quantity and at sufficient pressure, otherwise the welds may be porous, brittle, and burnt. The acetylene generator should be of good and solid construction, and the gasholder capable of storing all gas generated under working conditions or after stoppage of work. There should be no signs of polymerisation or overheating of the gas even when working at the maximum delivery. The cross-section of tubes, pipes, and passages through valves should be such that the gas flows normally at the maximum delivery without loss

of pressure. The pressure of gas should be as high as possible, and at least equal to 6 ins. of water pressure in the case of small plants, and 8 to 10 ins. in larger plants. The pressure should remain practically constant during working and not vary more than $\frac{1}{2}$ in. water pressure. The charging and cleaning of the plant should not result in any appreciable waste of gas, and be made without introducing sufficient air to interfere with the proper working of the blowpipe. The generator should comply with the Regulations of the British Acetylene and Welding Association. The size of carbide suitable for the type of generator should be used. For commercial purposes carbide is broken and packed in the following sizes: 80/120, 50/80, 25/50, 15/25, 7/15, 4/7, 2/4, and 1/2 millimetres. The figures refer to the approximate mean thickness of a lump in millimetres. The 50/80 size is in general use for welding and cutting generators. The choice of carbide-to-water, water-to-carbide, etc., generating plants depend on several factors, such as location, class of work, etc.

The Carbic system of generation is based upon the use of a carbic cake, which consists of specially prepared and treated carbide compressed into cylindrical cakes. It is claimed that the process renders every particle of carbide impervious to moisture, so that generation can only take place while water is in actual contact with the cake. Freedom from danger in handling, and from after-generation, convenience in handling, elimination of waste, and purity of gas are factors which have led to the success of the system.

Overloading of the plant is a common cause of defective welds. In carbide-to-water generators an allowance of not more than 1 cu. ft. of acetylene per hour for each pound of carbide in the rated charge is recommended. In the case of water-to-carbide generators the maximum rate of gas consumption should be half this value. In well-designed generators the yield of acetylene gas from the generator will be 85 to 90 per cent. of the carbide yield. Practically, for every 10 lbs. of carbide used in the generator a yield of 4·0 cu. ft. of gas at the blowpipe can be assumed. The proper care, cleaning, charging, and maintenance of generators is of first importance if reliable welds are required. Leakages of acetylene should be traced by means of soap-suds and never with naked lights.

The acetylene generating plant should be installed in a well-ventilated shed or building, or in a lean-to having no direct communication with a workshop or adjacent building, and no unauthorised person should be allowed to enter the building or enclosure. Where artificial light is required in a generator house or near a generator, electric incandescent bulbs, encased in outer gas-tight globes, should be used. A conspicuous notice prohibiting lights or smoking should be exhibited on the outside of the generator house. Generators should be cleaned and charged in daylight. Electric switches, fuses, etc., should be placed outside a generator house, or they should be so constructed that risks due to sparking or fusing are avoided. To comply with existing regulations, a licence under the Petroleum Acts must be obtained from the local authority for the storage of carbide. A sliding scale of licence fees, varying from 5*s.* to £5, according to the quantity stored, has been fixed, and severe penalties for contravening any condition printed or endorsed on the licence by the local authority are included. A raised platform in the generator house should be provided for the storage of carbide. Drums containing carbide should not be placed in the welding shop or near a flame. Care must be exercised in opening drums to avoid striking sparks; a proper drum opener should be provided for this purpose. When the contents of an opened drum are not entirely used in charging the generator, the remainder should be transferred to a storage bin which can be sealed.

All users and prospective users of oxy-acetylene equipment should consult the memorandums issued by the Factory Department of the Home Office* and the Board of Trade.†

Purification of Acetylene.

The chief impurities found in acetylene gas are (*a*) those which affect the quality of the weld, such as sulphur, phosphorus, silicon, finely subdivided lime; and (*b*) those which affect the cost of the weld, such as hydrogen and hydrogen compounds, nitrogen and nitrogen compounds, and water vapour. An efficient chemical purifer must be provided capable of removing sulphur and phosphorus compounds, the acetylene must pass through an efficient water-scrubber to remove or partially remove the impurities soluble in water and, finally, the gas should be filtered to remove solid impurities not eliminated by washing or chemical purification. A first-class purifying material will generally remove chemical impurities, moisture, and lime dust which are a common cause of defective welds.

Purification of the gas must be efficient, and the care and maintenance of the purifying chamber is very important. The cross-sectional area of the purifier should be ample, and the depth of purifying material should not exceed that specified by the makers, otherwise loss of pressure and overheating of the gas will take place. The quality of the gas can be simply and quickly tested by the use of a white absorbent paper, saturated with a 10 per cent. solution of silver nitrate, exposed to the gas. Should the paper turn black after a few seconds' exposure, the gas is unsuitable for welding purposes.

Among the best known purifying materials are Heratol, Catalysol, Klenzol, and Suder. The three last are distinguished by their regenerative properties—that is, they recover their activity by simple exposure to the air, and thus can be used over and over again. In purifying acetylene the cost should be based on the volume of gas purified and not on the first cost of the material.

* Dangers from the use of acetylene gas and in oxy-acetylene welding in factories (Form 1704).
† Instructions to Surveyors. Repairs to Boilers (Circular 1596).

Preservation of Acetylene Apparatus.

The question of preventing the corrosion or deterioration of the material used in the manufacture of acetylene generators, purifying vessels, and other parts of the generating plant is important in view of the fact that according to the efficiency of the coating the life of the plant may be a question of months or years.

There are five cases to be considered, namely: (*a*) preservation of the external parts of the apparatus; (*b*) preservation of the immersed parts; (*c*) preservation of parts in contact with moist and impure gas; (*d*) preservation of the interior of purifying vessels; and (*e*) preservation of carbide containers. With regard to (*a*), good ironwork paints give good results when applied well to properly prepared surfaces. At least two coats should be applied. If the apparatus is exposed avoid paints used for woodwork, plaster, etc. For (*b*) it is necessary to use a waterproof paint which will resist the prolonged action of water. The best results are obtained when the base consists of tar and graphite. For (*c*) the paints used for immersed parts of acetylene apparatus give the best results, but the work must be done with great care. For (*d*) the majority of industrial preservative paints give satisfactory results, except those containing a zinc or similar base. Several coats are necessary, and great care is required in applying the coats on to well-prepared surfaces. For (*e*) tests have shown that no paint or coating will satisfactorily resist the action of the lime residue at the temperatures usually present, and that the lime residue appears to have a preservative action on the parts with which it is in contact. It is therefore unnecessary to protect these parts.

Oxygen and Acetylene Regulators.

Regulators in common use to reduce the pressure of gases are of the diaphragm type, and may be roughly divided into two classes—first, where the pressure of the gas closes the inlet, and, second, where the inlet is closed by a spring. They are designed to automatically deliver gas to the blowpipe at any uniform pressure to which the regulator is set. They should be designed for working over a wide range of pressures, and should be sensitive even at low pressures. Oxygen regulators are usually equipped with two gauges, a high-pressure gauge, which shows the pressure of gas in the cylinder, and a low-pressure gauge. Pressure gauges should be provided with a check to prevent a sudden inrush of gas. For successful welding the regulator should be provided with a low-pressure gauge, giving the pressure at which the gas is delivered to the blowpipe. The range of the low-pressure gauge should not be too great, and a maximum reading of 75 lbs. per square inch will be sufficient for the majority of welding and cutting operations. Regulators must be kept in good order, otherwise defective welds are inevitable. Regulators intended for use when welding should not be used when cutting unless the work is within the range of the regulator. It is dangerous to use oil, grease, or any organic material for lubrication. If it becomes necessary to lubricate the pressure-regulating screw, or to repack a needle valve, a little glycerine should be used. The pressure-adjusting screw should always be released after ceasing work and before changing from one cylinder to another. Creeping regulators or regulators with leaky valve seats should be overhauled, because they are likely to become dangerous and uneconomical. The gradual increase of pressure when the blowpipe is shut off indicates a creeping regulator. Regulator gauges should be tested at regular intervals but never tested with an oil-testing pump.

Acetylene regulators are usually painted red and have a left-hand screw thread corresponding with that on the standard valves of acetylene cylinders. Regulators for oxygen are usually painted black and have a right-hand screw thread. Any possible confusion is obviated by this distinction.

Cylinder valves should be opened very slowly so that pressure does not suddenly come on to the gauges or diaphragm. The proper working of regulators largely depends upon the care given them. They should not be left in places where dirt or dust may get into the interior and be deposited on the seat or inlet nozzle, and they should never be repaired by inexperienced workmen.

Hydraulic Safety Valves.

These are indispensable in low-pressure and medium-pressure installations, i.e. where the acetylene is generated on the premises. Their function is to provide a water-seal and to prevent explosive mixtures entering the acetylene piping or generating plant. The valve should be chosen so that the maximum supply of gas is obtained without burning the metal. Safety devices based on mechanical principles, such as valves, etc., may more or less prevent the return of the flame, but are not infallible in preventing explosive mixtures forming in the generating plant.

Hydraulic safety valves should be charged and examined daily, and should be installed so as to facilitate filling to the proper level. The local authority responsible for issuing the carbide licence generally insists on the provision of a metal shield for the valve, to avoid accidents in the event of the valve being fractured. In general, the valve should be charged with water whilst the acetylene tap admitting gas to the valve is open. The design should be such that no water is carried over with the gas. A recent investigation has shown that the water vapour contained in the gas rises with the temperature, and can attain 7 per cent. when the gas is at 97° F. With a 5 per cent. of water vapour, there is a reduction of over 8 per cent. in the speed of welding. No safety valve should have more than one outlet to which a blowpipe can be connected.

Pressure relief valves or safety valves used on pressure generators should be tested periodically; they do not replace the hydraulic safety valve, which is still required in a modified form.

Piping and Flexible Tubes.

The acetylene piping should be large enough to avoid loss of pressure. The size of pipi should be dependent upon its length and the maximum supply of gas required. All piping shoul when possible and convenient, be run overhead. When piping has to be run underground should be placed in properly ventilated trenches. Piping and connections should be installed l workmen experienced in the installation of acetylene apparatus. Piping should be so arrang that any moisture will drain back to the generator, and where low points cannot be avoided the must be drained through drip cups closed with screw caps or plugs. No pet cocks should be use A main gas cock should be arranged where it can be conveniently reached and near the point entrance, so as to allow for shutting off the gas supply from any workshop. Gas cocks shou be provided on the branch tube leading to the hydraulic valve so that a valve may be remov without discharging the line. All cocks, valves, unions, and joints should be full bore, and t installation should be thoroughly tested when the system is completed, and at regular interval It should not show a loss of pressure exceeding two inches of mercury within twelve hours wh subjected to a pressure equal to a column of fifteen inches of mercury. Acetylene piping shou be painted a distinctive colour. Galvanised iron pipe with welded or threaded connections shou be used for piping acetylene. The pipes should be of uniform diameter, and bends—the numb of which should be as small as possible—should be used in preference to square elbows. Co pressed oxygen should never be used for testing or cleaning acetylene piping. If compressed a is used for this purpose the acetylene plant should be disconnected.

The following table will serve as a guide in installing acetylene piping for welding purpos Manufacturers of welding equipment will supply full particulars as to pipe sizes suitable for a particular lay-out.

Acetylene Main Piping.

Approximate Diameters of Service Piping. For working pressure of 6 in. to 10 in. water column

Consumption of Acetylene per hour.	Length of Pipe.	Internal Diam. of Piping.
Cubic feet.	Feet.	Inches.
15	100	$\frac{1}{2}$
40	100	$\frac{3}{4}$
80	100	1
140	100	$1\frac{1}{4}$
225	100	$1\frac{1}{2}$
400	200	2
1000	200	3
2500	200	4

Ordinary black steel piping may be used for low-pressure oxygen, and extra heavy steel pi for high-pressure lines. The suitability of steel piping for this purpose is being investigated. N oil or grease must be used for the connections; litharge and glycerine should be used. Th diameter of oxygen piping will depend on the length of the lines. A $\frac{3}{4}$-inch pipe is suitable f supplying twenty welding stations provided the length of the line is not more than 300 ft. an the maximum consumption is not more than 500 cu. ft. per hour.

The flexible tubes conveying the gases to the blowpipe should not be too long, too flexibl or too rigid. The strength should be such that for welding purposes the tube should withstand pressure of 100 lbs. per sq. in. without bursting, swelling, or leaking, and for use in cutting operatio it should withstand 300 lbs. per sq. in. Armoured or wired hose is not necessary or recommende for ordinary welding and cutting operations. Three-ply tubing with a core of pure rubber satisfactory for ordinary work, and for welding and cutting in confined spaces fire-resisting ho should be used. Avoid greasing the ends of the tube to facilitate fixing to the blowpipe or oth connectors; use water. Tube clips should be used in preference to wire, etc., for securing th tube firmly to the connectors.

Flexible tubing should be examined regularly, and defective tubing should never be use Avoid tangling or kinking the hose, long lengths—about 10 ft. lengths are suitable for stationar equipment and 15 ft. for portable—dragging the hose along the floor, and exposing it where it likely to get damaged. Special care should be taken to avoid the interchange of the oxygen an acetylene tubes when connecting up to the blowpipe. Both acetylene and oxygen tubing shoul be blown through occasionally, so that dirt and dust will not get carried into the blowpipe, an tubing should be tested periodically.

Welding Blowpipes.

Welding blowpipes are classified in relation to the pressure of the acetylene. Low-pressur blowpipes are those fitted with an injector to aspirate the acetylene, which is supplied from generator under a pressure of 6 to 12 inches of water. Medium-pressure blowpipes, sometime called positive pressure, use acetylene generated from a pressure generator at a pressure up t

9 lbs. per sq. in. An injector or partial injector forms part of the blowpipe. Recent developments have led to the introduction of blowpipes which use the acetylene at a pressure little different from that used with positive pressure blowpipes, but with the important difference that the oxygen pressure is considerably reduced, being, in fact, less than the acetylene pressure. High-pressure blowpipes use the acetylene supplied from acetylene cylinders, and are designed to mix acetylene and oxygen in equal volumes. No injector is required, and a change of nozzle with a corresponding adjustment of pressures is all that is required when changing over from welding one thickness of material to another.

In the low-pressure system thorough mixing of the gases in the blowpipe is very necessary. To obtain this, well-designed blowpipes carefully adjusted to the oxygen pressure recommended by the maker are essential. A typical low-pressure blowpipe working on the injector principle is shown in fig. 4.

The size or power of blowpipe which should be used depends upon the thickness to be welded. By power is meant the amount of acetylene consumed per hour. Too small a power produces the defects of adhesion, inclusion of oxide, overheating, and burning of the welds. Too large a power produces a molten bath which is much too large, holes, and adhesion in the lower part of the weld.

The figure denoting the power of blowpipes is usually supplied by the maker, and is sometimes marked on the blowpipe. In welding materials other than wrought iron and steel the power of blowpipe to be used is dependent upon the material, its dimensions, and whether the job has been preheated; as a general rule the power of blowpipe for a given thickness of material is greater, as in melting, for example, cast iron, copper, or aluminium, more heat is required to melt a given weight of the metal, and, in addition, the high temperature part of the flame is held farther from the molten metal.

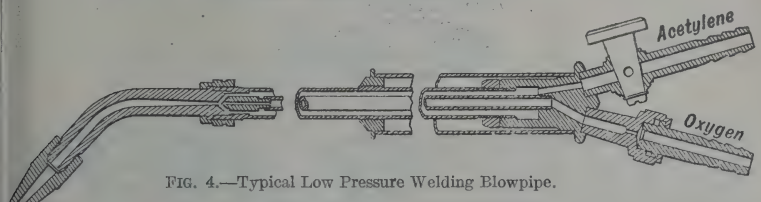

FIG. 4.—Typical Low Pressure Welding Blowpipe.

All blowpipes should be carefully handled and treated as precision tools. The procedure to be followed in lighting and extinguishing the blowpipes varies with the design and type of blowpipe. The manufacturer's instructions should be closely followed. Lighting devices are convenient and safer than matches. A blowpipe should never be put down, unless a blowpipe stand is provided, until the gases are turned off, and should never be hung from regulators or other equipment. Gas economisers which serve the purpose of a stand and automatically cuts off the gases, except sufficient acetylene for a pilot jet, are valuable, especially in repetition work. Carefully avoid the use of grease or oil, and never dismantle a blowpipe with a view to overhauling, as this may lead to irregular working after assembling. In the event of obstruction of the nozzle, a soft brass wire should be used for cleaning. Dust in the interior of the blowpipe can be removed by blowing oxygen through from the nozzle end.

In the case of back-firing or flash-back due to overheating, the tip should be cooled in water, taking care to close the acetylene valve and to leave the oxygen valve slightly open. By back-fire is meant the momentary return of the flame into the blowpipe tip, which may relight immediately upon withdrawing the blowpipe away from the work or necessitate the reignition of the gases by means of a lighter. By flash-back is meant a sustained back-fire, the flame burning in the mixing chamber with a squealing sound accompanied by a smoky, sharp-pointed flame, necessitating the immediate cutting off of the gas supply, to prevent severe heating and possible destruction of the blowpipe head, and the subsequent cleaning to remove carbon deposits. An iron or steel wire should never be used for cleaning the nozzle.

Back-firing and flash-backs, which are a common cause of defective and expensive welds, may be due to one of the following causes:—

(*a*) Faulty design and manipulation of the blowpipe.
(*b*) Enlarging the nozzle orifice when removing obstructions.
(*c*) Working in confined spaces or with an accumulation of slag on the nozzle.
(*d*) Necessity for overhauling and internal cleaning.
(*e*) Restriction and fluctuation in the acetylene supply due to bad lay-out, exhausted purifier, etc.
(*f*) Defective hydraulic safety valves leading to air and moisture being carried with the gas.
(*g*) Defective oxygen regulators.
(*h*) Presence of solid matter in the gas either from the acetylene generator or inferior flexible tubing.

Oxy-Acetylene Flame Characteristics.

The combustion of acetylene in oxygen produces a flame which consists of two parts—an inner cone, incandescent, clear, and well defined; and a non-luminous outer envelope which may be transparent or more or less opaque according to the purity of the acetylene. The exact character of the flame will depend on the proportion of the oxygen and acetylene as they emerge from the nozzle. The oxygen and acetylene should mix in approximately equal proportions. Gas-ratio, or the ratio of the oxygen to the acetylene consumption, is an important factor in determining the quality and cost of welds. Varying proportions of the gases produce three characteristic types of flames, commonly known as carbonising, neutral or normal, and oxidising. These are shown in fig. 5. It is important that at all times the flame should be neutral—that is, there

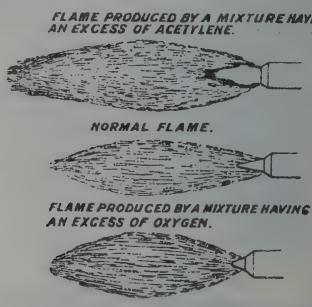

Fig. 5.—Flame Characteristics.

should be no excess of oxygen or acetylene. Defective welds are produced with carbonising and oxidising flames. It is particularly important that there should be no excess of oxygen, which not only tends to produce weak welds, but also to blow the metal forward and produce adhesion. Regulation of the flame during important welding operations is essential, as very few blowpipes maintain a neutral flame under welding conditions, and further, the operator has a tendency to adjust the flame oxidising. It is advisable to adjust the flame whilst wearing dark glass goggles.

It is necessary to emphasise that the white cone of the flame should never be brought into contact with the molten metal, and that its distance from the molten metal depends, in general, upon the metal being welded and its thickness.

Goggles and Protective Equipment.

For welding with acetylene it is necessary to protect the eyes with goggles fitted with suitable coloured glasses. There are a great many different kinds of special safety glasses on the market and many combinations of ordinary coloured glass are in common use. The eyes must be protected from injurious rays, the heat and glare from the work, and from particles of hot metal that fly up from the weld. To obtain the clearest definition or visibility with the least amount of glare, the selection of the colour tint in safety glasses should properly be decided by an expert; the depth of the tint may be determined best by the operator himself, owing to the individual difference which will permit one man to see clearly through a glass that would be too dark for another man. Amber, dark-amber, or dark-amber-green glasses give efficient protection. Glasses showing blue or violet tints should be avoided, except in certain combinations where they are used to obscure other colours.

Welders employed on heavy work should be supplied with fireproof gauntlets and aprons, as a protection against radiated heat, and where welding is being performed in the interior of some structure or confined space all the outer clothing should be fireproof.

Filling Materials.

The necessity for employing the best materials for every welding operation cannot be too strongly emphasised. It is only by using the most suitable filling-in wires, rods, and fluxes, specially manufactured and controlled for each particular metal or alloy, that the most satisfactory work can be done.

Thin material is frequently welded by bringing the edges into contact and melting them together, but generally a filling material or 'welding rod' is melted into the groove or crack.

Filling materials must, where possible, not only be of the correct chemical requirements to replace loss in the molten zone, to counteract the tendency of the metal to oxidise, to assist in

FERROX WIRES *for* FINE WELDING.

FERROX IS THE FEEDWIRE SPECIALLY REFINED AND TREATED FOR WELDING OF MILD STEEL, WROUGHT IRON AND MALLEABLE CAST IRON.

Feed-Rods and Fluxes for Grey Cast Iron, Aluminium, Phosphor-Bronze, Brass, Copper, Nickel and Chromium Steels.

making the molten metal flow readily, or to break down oxides when formed, but they should also act satisfactorily under the blowpipe. As a general rule, the welding wire or rod should have practically the same composition as the material to be welded.

The choice of the right size of welding wire or rod is important, and melting of both should take place in the molten bath and not in the flame. The following table gives the sizes of wire for 'forward' welding iron and steel. In the case of other metals the figures hold good, except for very thin material, when a size of not less than $\frac{1}{16}$ in. should be used.

SIZES OF WELDING WIRE FOR IRON AND STEEL ('FORWARD' WELDING).

Thickness of Material.	Size of Welding Wire.		
	S.W.G.	Decimal equivalent.	Nearest $\frac{1}{64}$.
Gauge 20 to Gauge 18	16	0·064	4
$\frac{1}{16}$ inch	15	0·072	5
$\frac{1}{8}$ "	12	0·104	7
$\frac{3}{16}$ "	9	0·144	9
$\frac{1}{4}$ "	6	0·192	12
$\frac{5}{16}$ "	5	0·212	14
$\frac{3}{8}$ "	3	0·252	16
$\frac{7}{16}$ " to $\frac{1}{2}$ "	2	0·276	18
$\frac{9}{16}$ " to $\frac{5}{8}$ " to $\frac{3}{4}$ "	0	0·324	21

The following table also gives the sizes of wire for 'backward' welding; it should be pointed out that this method of welding is more reliable and economical than 'forward' welding, and is rapidly displacing the latter for welding iron and steel of medium and heavy thicknesses.

SIZES OF WELDING WIRE FOR IRON AND STEEL ('BACKWARD' WELDING).

Thickness of Material.	Size of Welding Wire.		
	S.W.G.	Decimal Equivalent.	Nearest $\frac{1}{64}$.
Gauge 20 to $\frac{1}{8}$ in.	14	0·081	5
$\frac{3}{32}$ in.	11	0·116	8
$\frac{1}{4}$ to $\frac{5}{16}$ in.	8	0·160	10
$\frac{3}{8}$ in.	6	0·192	12
$\frac{9}{16}$ to $\frac{3}{4}$ in.	4	0·232	15

Fluxes.

It is not always possible to include deoxidisers and special elements in the welding rod itself. By using a combination of chemicals in the form of a powder, liquid, or paste, known as a flux, the difficulties of producing sound and reliable welds are frequently overcome. A flux is used for (*a*) cleaning the parts to be welded; (*b*) eliminating and preventing the formation of oxide; (*c*) replacing elements burnt out by the flame; (*d*) facilitating the flow of the metal, and, when melted, (*e*) protecting the surface of the molten metal from the action of the flame and preventing blow-holes. The mantle of a well-regulated and well-manipulated flame protects, in a measure, the molten metal from oxidation. A flux is necessary in welding steel (except in cases where the steel welding wire contains deoxidising materials, as, for example, Ferrox), cast iron, copper, aluminium, etc.; for successful welding the proper flux should be used, and as the welding rod and flux are important factors in welding they should only be obtained from reliable manufacturers.

Preparation of the Work.

One of the first principles of sound welding is securing complete fusion and perfect union o the filling material and the edges of the parts to be welded. To ensure this, good preparation i necessary, which includes, as a rule, the cleaning of the edges and the welding wire, the bevelling or chamfering of the edges, the adjustment and maintenance of the parts in position, and allow ance for expansion and contraction effects. In general, the preparation of the parts varie according to the thickness and nature of the metal and with the organisation and equipmen of the workshop.

Cleaning the parts to be welded and the welding wire or rod is essential. Bevelling is necessary for materials $\frac{1}{8}$ inch and above in thickness. Bevelling ensures good penetration, increase i ductility and strength, economy, and reduction in the overheating effects. The angle of th bevel depends upon the thickness of material and whether 'forward' or 'backward' welding i practised. All metals from $\frac{1}{8}$ inch up to $\frac{3}{8}$ inch, and in some cases $\frac{1}{2}$ inch, should be bevelled fron one side only. Where possible, pieces exceeding $\frac{1}{2}$ inch should be bevelled from both sides In forward welding the V formed by the two bevelled plates should be about 90°. In backward welding for material up to $\frac{1}{4}$ inch an angle of about 45°, and above $\frac{1}{4}$ inch an angle of 60°, can be used. The bevel should extend to the bottom of the plate, and thorough penetration and complete fusion should be obtained. In repair work preparation of the work is a very important feature and will save considerable time and keep the cost of welding low. Should it be necessary to re-weld a joint previously welded, it is essential that the weld metal be entirely removed, and on old work the same instruction applies, and corroded metal must be removed. In the case of aluminium repairs, for example, good judgment, as shown by the preparation, means success and bad judgment a ruined casting.

Expansion and Contraction.

It is impossible to produce satisfactory work unless expansion and contraction effects are properly allowed for. Warpage and residual stresses, followed by failure, are the common result of welders failing to master this subject. The methods commonly employed are, in the case of thin sheets, tacking; in the case of heavier material and castings, setting the plates so as to form an angle, heating the entire work, partial heating, heating restraining members, breaking a member so that expansion and contraction can take place freely, bending or springing the material, etc.

If expansion can take place in all directions, it will give the welder no trouble, but he should operate so as to leave practically no residual stresses. If, however, welding takes place at a point that is confined by various parts or by the particular construction of a piece, it is necessary to give it due consideration.

The effects of contraction must be considered equally with those of expansion, as failures, cracks, etc., can often be traced to neglect of this property.

Preheating.

This may be partial or total, depending upon the work in hand, and is mainly employed with a view to (*a*) allowing for expansion and contraction, (*b*) decreasing the cost of welding, and (*c*) producing a more homogeneous joint. Preheating is usually carried out with the welding blowpipe, oil or gas burners, charcoal, or other suitable fuel. Where fuels such as charcoal are used for preheating, the combustion gases should, where possible, be carried away. In any case ventilation should be provided to avoid the harmful effects of the gases produced by combustion. The method used should be governed by the particular work in hand.

No general rules can be given for preheating temperatures, as the degree of heat necessary will, of course, depend upon the size and shape of the object to be welded. As a general rule, however, cast iron should be preheated to a dull red heat for small and simple castings, and to a blood-red heat for large or complex castings; aluminium and its alloys should be preheated very carefully, as too high a temperature will lead to the collapse or distortion of the article being welded.

Preheating machines burning paraffin and giving a flame of high calorific value, smokeless and transparent, give satisfactory results where portability and a powerful flame are required.

After-Treatment of Welds.

Improvement in the structure of welds with a consequent increase in strength and ductility is the result of proper after-treatment of welds. Thermal or mechanical treatment, or both, carried out in a correct manner is invariably beneficial, except in the case of defective welds.

Strength of Welds.

With proper equipment and suitable filling materials, the strength of a weld will depend mainly upon the care and skill of the operator. A good operator should be able to obtain welds 95 per cent. the strength of the original material on material of good weldability; for the average welder 85 per cent. should be taken as the lower limit of strength.

Recognition of Materials.

Some of the means by which the materials of the parts to be welded may be recognised are follows: colouring, appearance of surface, contour, grinding spark test, chisel cut, fracture, owpipe test. The identification of the metal, especially in repair work, is invariably indispens-le. Once the metal or alloy is known the next step is to get familiar with all the facts relating its weldability and, in case of doubt, proceed to the necessary tests for determining these.

Steel Welding.

The welding of wrought iron and mild steel is apparently simple; in reality it is somewhat fficult to produce strong and reliable welds. Oxidation and inclusions are the most serious fects, and must be reduced to a minimum. Welding wires containing a small percentage of nadium or nickel are used with highly satisfactory results. To produce the minimum oxida-n the blowpipe must be well designed and handled efficiently and the parts to be welded must thoroughly cleaned. Expansion and contraction must receive proper consideration. The e of a flux in the form of a powder has not proved satisfactory. It has been found that de-idising materials in the form of a liquid gives excellent results. The product known as 'Suder' specially prepared for use with a welding wire which does not contain deoxidising elements. t the high temperature of the flame it slags the oxide, keeps the surfaces clean, and prevents e inclusion of oxide. The weld can be carried out rapidly, thus reducing overheating effects. ne liquid is applied by means of a brush to the edges of the plates and the welding wire previous welding. The welding wire should be a material low in phosphorus and sulphur, and free m oxide. The use of ordinary iron or mild steel is unsatisfactory, and welding wire, such as tylax,' 'Suder' or 'Ferrox,' made especially for the oxy-acetylene process, should be insisted on. It will be found that economy is on the side of the scientific but slightly more stly, and dependable, product.

The following abstract from a specification for a welding wire for iron and mild steels is of terest and represents the American Welding Society's Specification for the welding wire for oxy-etylene welding mild steel, structural work, plates, bars, low carbon steel forgings and castings. ne surface of the wire is to be smooth, of uniform homogeneous structure, free from irregularities surface hardness, segregation, oxides, pipe, seams, etc. Diameter shall not vary more than 3 per cent. of the diameter specified. The chemical composition to be within the following nits :—

Carbon	not more than	0·06 per cent.
Silicon	,,	0·08 ,,
Manganese	,,	0·15 ,,
Sulphur	,,	0·04 ,,
Phosphorus	,,	0·04 ,,

The surface shall be smooth and free from scale, rust, oil, or grease. In the hands of an perienced welder the wire shall demonstrate good weldability, and shall flow smoothly and enly without any unusual characteristics.

For welding mild steel and to produce a weld of greater strength but of lower ductility than at obtained with ordinary welding wire, the wire should contain 0·15 to 0·25 per cent. of carbon, 25 to 3·75 per cent. of nickel and 0·5 to 0·8 per cent. of manganese.

A simple test to indicate the fitness of welding wire is made by laying the wire flat on a clean rface and applying a good neutral oxy-acetylene flame to the wire in such a manner as to heat up for a distance of about 3 or 4 ins., playing the flame backwards and forwards until the wire red and then slowly melting the wire, moving the flame so that the wire only melts halfway rough its diameter. If the flame is withdrawn as soon as the metal begins to melt, the impurities n readily be seen being thrown off in the form of sparks, or a boiling action in the case of in-rior metal; and in some cases the metal will not flow together, but 'runs away.' The metal om gas absorbing wires will, when cold, contain numerous spongy, volcano-like irregularities. n the case of clean metal free from impurities the wire will melt and flow evenly without any isturbing action.

The following table is useful when ordering welding wire:

Size. Inches	$\frac{1}{16}$	$\frac{3}{32}$	$\frac{1}{8}$	$\frac{5}{32}$	$\frac{3}{16}$	$\frac{1}{4}$	$\frac{5}{16}$	$\frac{3}{8}$
Lbs. per 100 ft. .	1·04	2·3	4·1	6·5	9·3	16·7	26	37·5
Ft. per 100 lbs. .	9,615	4,273	2,403	1,537	1,067	600	383	266

The flame must be carefully regulated and held so that the tip of the white cone is about $\frac{1}{8}$ in. om the surface of the molten metal.

A good practical rule in welding steel is that the hourly consumption of acetylene should e 4½ to 5½ cu. ft. (120 to 160 litres) for every $\frac{1}{16}$ in. in thickness.

The following useful table is made up from these figures, in which the approximate bore of ne nozzle orifice is included:

POWER OF BLOWPIPE FOR IRON AND STEEL.

Thickness of Material in Inches.	Consumption of Acetylene per Hour.		Bore of Nozzle in $\frac{A}{64}$ inch.
	In Litres.	In Cubic Feet.	
22 gauge	60–80	$2\frac{1}{8}$–$2\frac{3}{4}$	2
$\frac{1}{16}$	120–160	$4\frac{1}{4}$–$5\frac{1}{2}$	3
$\frac{1}{8}$	240–320	$8\frac{1}{2}$–11	3 full
$\frac{3}{16}$	360–480	$12\frac{3}{4}$–$16\frac{1}{2}$	4
$\frac{1}{4}$	480–640	17–22	5
$\frac{3}{8}$	720–960	$25\frac{1}{2}$–33	6
$\frac{1}{2}$	960–1280	34–44	7
$\frac{3}{4}$	1200–1600	$42\frac{1}{2}$–55	8

The blowpipe must be given a motion which will cause the flame to describe a series of ove lapping circles in the case of light and medium sheets, and oscillated in a series of overlappin semicircles in the case of heavy sections. This is known as 'forward' welding. A variation c these movements has been introduced which gives more economical and better welds. Th welding wire, in this case, follows the flame instead of preceding it, and the flame is directe towards the starting point instead of towards the finishing point. The blowpipe is given a sligh gyratory motion, whilst the welding rod is given a more or less elliptical or longitudinal motion This method of welding is known as 'backward' welding. Subsequent thermal treatment, whic may consist of annealing or normalising, according to the particular requirements, will improv the structure of steel welds and materially increase the strength and toughness of the weld Hammering may be resorted to with good effect, provided the hammering is not too vigorous o done at too low a temperature.

The following table gives the speed at which the welding of mild steel plates can be don under average conditions:

Thickness of Plate in Inches.	Speed of Welding.	
	Feet per Hour.	Feet per Hour for Average Day's Work.
$\frac{3}{64}$	30 to 33	23 to 26
$\frac{5}{64}$	20 „ 21	16 „ 20
$\frac{1}{8}$	15 „ 16	13
$\frac{5}{32}$	13 „ 15	10
$\frac{13}{64}$	10 „ 12	9
$\frac{1}{4}$	9 „ 10	$7\frac{1}{2}$
$\frac{9}{32}$	8 „ 9	$6\frac{1}{2}$
$\frac{21}{64}$	7 „ $7\frac{1}{2}$	6
$\frac{3}{8}$	$5\frac{1}{2}$ „ 6	5
$\frac{13}{32}$	$4\frac{1}{4}$ „ $4\frac{1}{2}$	$3\frac{1}{4}$
$\frac{1}{2}$	$3\frac{1}{4}$ „ $3\frac{1}{2}$	$2\frac{1}{2}$ to 3
$\frac{19}{32}$	$2\frac{1}{4}$ „ $2\frac{1}{2}$	$1\frac{1}{2}$ „ 2

Owing to metallurgical changes that take place when melting medium and high carbon steel with the blowpipe, the welds obtained are invariably unsatisfactory. As a general proposition, the lower the carbon content of the steel, the more successful the welding operation. It is possible to get fair results on medium steels, but a flux, rapid welding, and thermal after-treatment, which requires skill to properly carry out, are necessary.

The data at hand show that for welding medium carbon steel, welding wires having a carbon content ranging from 0·06 to 0·60 per cent. are of no particular value.

For welding high carbon steel and worn surfaces where great resistance to abrasive wear is desired and where machining is not necessary, a welding wire containing 0·60 to 0·75 per cent. of carbon and 0·60 to 0·90 per cent. of manganese is desirable.

Alloy steels, such as chrome and manganese steel, are weldable, provided the percentage of carbon does not bring them into the range of medium and hard steels, which is frequently the case. The welding wire should be of the same character as the steel, and a flux must be used. In the case of nickel steel it is necessary to use a flux which will form a varnish over the molten metal and prevent the absorption of the gases from the flame of the blowpipe. It is important to recognise that alloy steels are used largely because of the excellent physical properties that are developed by suitable heat treatment, and that the uneven heat treatment produced by welding temperatures may produce considerable variations in quality. Hence they should be welded with a full knowledge of the alloy and the results likely to be obtained. This also applies to the welding of stainless steel.

Cast-Iron Welding.

The two principal defects in cast-iron welding are the production of hard spots and blowholes the weld and subsequent cracks or fractures in the weld or adjacent metal. The oxide formed ust be removed or destroyed by the use of a flux. The welding rod must be of good material id specially made for cast-iron welding. One great trouble with cast-iron rods in general is iat the quality is by no means uniform. This is especially true with the cheaper and uncon- olled products. Rods made from ordinary cast iron produce blowholes and hard spots. Special ds containing titanium, producing sound, soft, and reliable welds, are obtainable. Expansion id contraction should be considered as of great importance. Preheating should be used to some :tent in all cast-iron welding. It is advisable to weld in position after preheating. The welder protected by making use of asbestos sheet or simply plate. Specially designed blowpipes of nsiderable length are available for this class of work, and two or three welding rods are welded gether. The parts must be thoroughly cleaned, and in the case of cracks their extension must be evented by drilling holes a short distance from the ends in the direction the crack would follow. ie weld should be arranged horizontally, and where this cannot be arranged carbon blocks ould be used to prevent the metal flowing away. Carbon products, in the form of blocks, wder, or paste, play an important part in modern welding operations. They are far superior to e-clay or fire-bricks, which are liable to melt under the blowpipe and invariably cause blowholes. rbon compound, in powder form, which can be made into a plastic mass with water, is valuable r making moulds, dams, etc., and for lining up repairs and holding parts in position. To pro- ct machined surfaces during preheating operations, they should be coated with flaked graphite d oil. This can be made into a paste and painted on, or the surfaces can be oiled and the aphite dusted on. The graphite must be coarse, as fine flake is not satisfactory. The flame ist be held so that the tip of the white cone is between $\frac{1}{4}$ and $\frac{3}{4}$ in. from the molten metal, the stance depending on the thickness of the metal. The after-treatment consists in annealing or owing the metal to cool very slowly. In well-executed welds on cast iron the quality of the ld is generally superior to that of the metal of which the casting is made. The grain is finer d the welded zone is sound, homogeneous, and can be easily worked.

Certain cast irons of great strength and in which the carbon is in the combined state are actically unweldable. Cast iron which has been submitted to the heat of a fire for a consider- le time is frequently unweldable. The metal in both cases melts under the blowpipe in a dis- ctly different manner from ordinary cast iron, and the welder should have no difficulty in cognising that the blowpipe should not be applied to make a joint. The bronze 'welding' cast iron, iron, steel, etc., is a process in which the oxy-acetylene flame is used in conjunction th a copper-zinc alloy, such as Tobin or manganese bronze, to produce joints which would be ficult or expensive to obtain by the usual method of melting the parent metal. The procedure making joints is very much the same as in actual welding. The 'V' opening need only be out 15 degrees. See also p. 2019.

Malleable Cast Iron.

It is difficult to produce satisfactory joints on malleable cast iron by welding. The welds are ed, brittle, and porous. The best results are obtained by brazing with the oxy-acetylene wpipe, using the same methods of preparation as for cast iron, and using manganese bronze a filling material. The two pieces to be joined are brought to a point just below fusion, great e being taken that they do not become fused. When the edges are at a right temperature, rod of manganese bronze is fused into the groove with the aid of a good flux.

The introduction of acetylene for brazing purposes provides a fuel which has the highest own flame temperature and high calorific value. By using dissolved acetylene with a special azing blowpipe no air-bellows or oxygen is necessary, as the blowpipe is atmospheric and a an and relatively small flame of suitable power is obtained.

Aluminium Welding.

Sheet aluminium welding can be handled in very much the same way as steel as regards paration and allowance for expansion and contraction. The principal difficulty lies in the mation of the oxide, which must be dealt with by an energetic and reliable flux. The filling terial is pure aluminium wire; before starting to weld, the wire and parts to be welded must thoroughly cleaned by scraping. A delicate touch and considerable practice are necessary, ecially on thin material. Material under 22 gauge is best welded after flanging the edges. e flanged edges should practically have no radius, so as to leave the minimum of space between underside of the sheets. The depth of the flange should be about two and a half times the ckness of the sheet. The white cone of the flame should be level with the surface of the plates d the blowpipe held so that the flame is inclined to the horizontal at about thirty-five degrees. he methods are correct the upper and lower surfaces of the weld appear identical. The power the blowpipe to be used is not in direct ratio to the thickness of the metal as in steel welding. r example, on 16 to 19 gauge material a blowpipe consuming 2 cu. ft. of acetylene per hour uld be satisfactory, whilst for material $\frac{1}{8}$ in. thick 10 cu. ft. is required, and for $\frac{1}{4}$-in. material cu. ft. per hour. The flame must be carefully regulated, and the tip of the white cone uld be from $\frac{1}{4}$ to $\frac{3}{4}$ in. from the molten metal. After welding, the welds should be thoroughly shed with warm water and, where possible, internal strains should be removed by annealing.

The structure and strength of the metal in the welded zone are improved by hammering whe cold. Subsequent corrosion of the welded seams may be due to the physical condition of th aluminium sheet.

Pure aluminium is not usually employed for castings subject to stress. In order to raise th tensile strength and increase the hardness varying percentages of zinc, copper, or nickel are adde There is an endless variety of aluminium alloys, but from a welding point of view they fall int two classes, viz., those containing zinc as their principal hardening medium and those containin copper. The material expands greatly and is very weak at high temperatures, consequentl contraction strains are likely to produce cracks and distortion unless the work is properly handle In welding castings—crank cases, for example—it is often necessary to preheat them eithe completely or partially. The preheating must be done carefully, otherwise the casting ma collapse. For supporting the casting evenly and lining up, carbon putty is useful. For missin parts, and where the welder is not well skilled in this class of work, it is advisable to back u with sheet copper or galvanised iron. In rigging up jobs for repairs, care must be taken tha expansion and contraction effects are not interfered with. The parts should be carefully cleane and free from oil and grease. The repair of oil saturated castings is frequently one of consider able difficulty. Cleaning, by dipping in caustic soda, followed by washing in scalding hot wate and drying, bevelling to a larger angle than usual and sweating out the oil and scraping it awa indicate the methods which lead to successful repairs. A good grade of filling material of averag composition is necessary; pure aluminium wire should not be used. The acetylene should b pure and the blowpipe should give a soft, non-oxidising flame. Two methods of welding ar adopted, one known as the flux and the other as the puddle method. In the former a flux used in the ordinary way and in the latter no flux is used, a steel rod and paddle being used t remove or break down the oxide and to smooth the weld respectively. All traces of flux mus be washed off. The casting should be reheated slightly to remove any local strains and the allowed to cool very slowly. For finishing off a single cut-file or a 'dreadnought' file is mo suitable.

The welding of the well-known aluminium alloy known as 'Duralumin,' which contains coppe manganese, magnesium, etc., is satisfactory or not according to the mechanical properties r quired in the joint. The alloy has important properties which are reduced, and in some cas almost eliminated, by welding operations. The metal should not be welded when the joints a subject to bending action, shocks, or when the full properties of the metal are desired.

Copper Welding.

Copper may be welded, but only satisfactorily where the operator is familiar with the techniqu Many failures can be attributed to the commercial metal being in an unsatisfactory conditi for welding. Where possible, a sample strip two or three inches long should be tested by maki a weld and applying a bending test. It is necessary to clean and bevel the edges and to suppo the underside of welds made on thin material, copper tubes, etc., by means of a mandrel co sisting of an iron tube on which is wound or fixed asbestos, which must be perfectly free fro moisture. Owing to its lack of strength when hot, the tacking of copper welds should be do carefully. For the same reason welds should not be started at the edges of the sheets, but at point about one-third the length of the seam. The power of the flame should be practically the sam as that used for welding steel of the same thickness. The flame must be carefully regulated. T melting should not be too rapid or too slow. Without a correct welding rod, which contains small quantity of phosphorus, it is impossible to satisfactorily weld copper. A flux is usefu Preheating to avoid adhesion is necessary. The tip of the white cone should be about $\frac{1}{4}$ i from the surface of the molten metal. The welds should be hammered at a dull-red heat improve their ductility and strength, and afterwards annealed. The technique for the repa of copper fireboxes and tube plates has been worked out and applied with great success. A goo sense of fusion, the addition of the metal in thin layers, and satisfactory equipment are essenti for success. Welds can be obtained with mechanical properties almost identical with those the metal welded. Such welds can be planished, stamped, spun and, in general, submitted the ordinary workshop operations carried out on sheet copper.

Brass and Bronze Welding.

Brasses and bronzes are only welded indifferently without the correct welding wire rods. The filling material should be practically of the same composition as the metal to welded, which, in the case of brass, should contain a little aluminium, and in the case of bronze little phosphorus and traces of aluminium. Bronze filling materials are cast. Fluxes shou be used in both cases, and the power of the flame is less than that used for the same thickne of copper—that is, distinctly less than for steel plates of the same thickness. The regulation the flame is very important: a slightly oxidising flame will give a surface free from wrinkles. T position of the flame is the same as for copper. The after-treatment of the welds consists annealing at definite temperatures. Identification of the particular brass or bronze to welded is important in view of the importance of choosing the correct welding wire or ro Reclaiming castings and repairing worn or broken parts, such as gear wheels, bearings, etc., co stitute the general run of the work on bronzes. In the case of castings similar methods to tho outlined for the repair of cast iron are necessary.

The BRITISH OXYGEN Co LTD.

ANGEL Rd EDMONTON, LONDON, N.18., & BRANCHES

ARE SPECIALISTS IN THE MANUFACTURE OF

GASES AND HIGH PRESSURE GAS EQUIPMENT

INCLUDING

METAL CUTTING AND WELDING PLANTS

FOR USE WITH ACETYLENE, HYDROGEN, OR COAL GAS: FOR LEAD BURNING AND BRAZING: FOR CAST IRON AND UNDER WATER CUTTING

GAS REGULATORS, MANIFOLDS, etc.

FOR ANY GAS, PRESSURE, OR CAPACITY

METAL CUTTING MACHINES

FOR CUTTING STRAIGHTS, CIRCLES, OVALS, PROFILES, BARS, TUBES, ETC.

GAS COMPRESSORS

FOR ANY GAS, CAPACITY, OR PRESSURE

OXYGEN

ALSO HYDROGEN, NITROGEN, HELIUM, CARBON DIOXIDE, NITROUS OXIDE, SULPHUR DIOXIDE, ARGON, NEON, ETHYLENE, LIQUID OXYGEN, AND COMPRESSED AIR

ALSO PLANTS FOR THE PRODUCTION OF THE ABOVE GASES

We also supply Carbide and Dissolved Acetylene

London Showrooms:

69 HORSEFERRY ROAD, WESTMINSTER, S.W.1

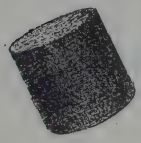
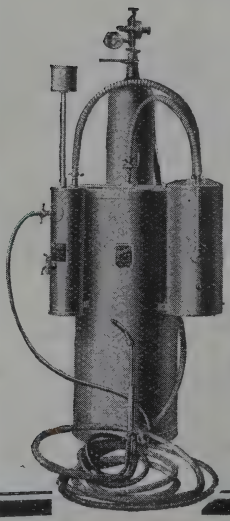
Use the CARBIC System of Cutting and Welding

BECAUSE acetylene obtained from Carbic Cake, a specially prepared and treated carbide compressed into cylindrical cakes, is proved by chemical analysis to produce acetylene five times purer than that from ordinary lump carbide.

BECAUSE the operation of the Carbic Generator is based on natural laws, which automatically ensure a regular and constant pressure of gas at the burner, however varied the demand.



The Carbic 5,500 reflected c.p. *Flare Light* and the 150 reflected c.p. *Handlamp* are other Carbic products of great usefulness to the engineer.



Write for full particulars of the Carbic System of Flare Lighting, and for a complimentary copy of the useful Carbic Cutting and Welding Book.

Lead Welding.

The oxy-acetylene blowpipe is rapidly supplanting the older methods of welding lead, or lead burning,' as it is generally called. It has proved superior in convenience, quality of joints, nd economy. A small type of blowpipe is required, consuming from $\frac{1}{2}$ to 6 cu. ft. per hour. When it is necessary to fill up a hole or to build up any part of a lead object, the work is facilitated by using a mould or a backing of steel plate. When welding patches in repair work avoid rectangular patches on vertical faces, which make two edges of the patch horizontal. The patch should be made lozenge shape, so that the welds are done on the incline. The welding wire or rod should be of the same metal as the sheet. Special outfits have been designed for lead burning, using dissolved acetylene; they are very compact and portable.

Nickel Welding.

Nickel when melted has the property of readily absorbing gases, especially oxygen. Various methods have been tried to protect the molten metal from the gases of the blowpipe and to prevent their absorption. The welds obtained are very porous, and it is extremely difficult to obtain satisfactory welds. A method which has given fair results consists in placing the two parts to be welded on a heated anvil and then heating the parts to a white heat with the blowpipe, afterwards carefully hammering the parts together.

Machines for Welding.

Acetylene welding machines for the manufacture of tubes have been in use for many years. The development of automatic welding machines for the manufacture of tanks, etc., is more recent. For repetition work machines have been designed which accomplish the work in less time with comparatively unskilled men. The machines consist of two parts, (*a*) holding device for the work, and (*b*) apparatus for moving the blowpipes, with or without oscillatory motion, over the seam.

Recent developments in welding machines have been mainly in the direction of the use of multi-jet blowpipes. In order to obtain speed it was recognised that more than a single jet of flame should be employed, and from two jets in tandem it has become customary to employ a large number of jets extending for a considerable distance along the line of the weld. The defects of this method have been overcome by distributing the heat on both sides of the centre line of the seam. The welded section produced in this way is wider, stronger, and more certain to penetrate than is the case with the narrow weld made by a central line of flame.

Training Welders.

An oxy-acetylene welder has been defined as a person who has the requisite manipulative skill and technical knowledge successfully to operate welding and cutting apparatus, and, at the same time, has skill in the operation of hand tools used in the preparation and finishing of the work in connection with welding, and also has a reasonable amount in ingenuity. He must also have a knowledge of accuracy commensurate with the type of work to be welded. Naturally, a trade in which so much depends on the personal equation has drawn attention to the need of training men to produce sound work. No doubt the best method is that which expounds principles followed by practice under expert supervision. Welding skill grows rapidly under a well-worked-out system of exercises which aim at developing skill in making typical welds on various metals. Testing the welds is also an important requisite of a training course. Classes for training welders are held in the principal centres, and manufacturing concerns who train their workmen must follow methods depending upon the size of shop and class of work.

A common error is to attempt work, especially repair work, in a shop where the tools and apparatus for successful all-round welding are not provided, or to endeavour to repair jobs which are beyond the capacity of the welder. It is much more economical, in such cases, to hand over work of this character to firms specialising in general repairs who have the necessary equipment for carrying out and testing the work, and welders who are not mere blowpipe operators.

Testing Welds.

The importance of testing welds has, in recent years, become very great. It is well known that the quality of a weld cannot be assumed from the general appearance, finish, etc., although considerable information can be obtained from the visual inspection of welds. At the present time the usual methods of testing include tensile and impact tests on specimens welded

under identical conditions, microscopic examinations of specimens, bending and hammering test and X-ray examination. In the latter the actual welds can be examined, and flaws, blowhole and other defects discovered. Recent investigations indicate that electrical and magnetic tes for the non-destructive examination of welds will soon find commercial application.

The American Bureau of Welding have drawn up Standards for Testing Welds which ar intended primarily to serve as a standard uniform basis for testing and comparing sample weld as distinguished from welds on structures. The testing of the latter must necessarily be b non-destructive methods, which would therefore be, in general, quite different from those employe in examining sample welds made for the purpose of testing a welder's proficiency, comparin welding wires, or comparing welding methods. For the shop standard a bending test is recom mended ; for the commercial standard, a bending and tensile test on approved lines.

Miscellaneous Applications.

There are numerous applications of the oxy-acetylene process not included in the term weld ing, but which have a direct or indirect connection with it and are worth consideration. Th oxy-acetylene flame, for example, is a convenient and simple method of applying local hea for numerous workshop operations, such as forging, straightening, riveting, expanding fo shrinkage fits, heat-treatments, etc.

Brazing operations are more efficiently carried out with the oxy-acetylene flame than by th older methods. Case-hardening and surface hardening can also be efficiently and economicall done with the flame.

OXY-ACETYLENE CUTTING.

Wrought iron, steel, and steel castings can be cut with the ordinary cutting blowpipe, an with a special cutting blowpipe or the ordinary cutting blowpipe operated in a special manne cast iron can be cut.

The cutting blowpipe usually consists of a compound jet made up of one or more heatin flames with a pure oxygen jet in the centre. The purity of the oxygen is of much greater import ance when used for cutting than when used for welding. As the purity decreases the oxyge consumption and time increases, and the speed of cutting decreases as the following figures, whic represent tests on steel plates 5 feet long by 1 inch thick, show :

No. of Test.	Purity of Gas. Per cent.	Time in Seconds.	Oxygen Consumption in Cu. Ft.	Remarks on Cuts.
1	99·7	280	8·0	Very smooth and clean.
2	99·4	291	8·8	Smooth.
3	99·1	315	9·8	Satisfactory.
4	98·0	334	11·3	Good but rough
5	96·0	365	13·2	Not smooth.
6	95·0	412	15·4	Very irregular.
7	90·0	644	20·0	Rough, surface bad.
8	87·0	675	23·0	Very rough, surface bad.
9	85·0	696	25·8	Very rough, unsatisfactory.
10	82·5	—	28·4	Very rough & not through.

A spot on the metal is first heated to a bright red heat with the heating flame, and then th oxygen jet is turned on. It has been proved that only partial combustion takes place, the pheno menon of cutting being really a disintegration by the current of gases from the blowpipes. Th oxy-hydrogen or oxy-coal-gas flame is often used for cutting in place of acetylene. Material up to 36 ins. has been cut. The same acetylene equipment is used for cutting as for welding. Fo heavy cuts special oxygen regulators are required. There are two kinds of cutting blowpipes known as the 'central' and 'following jet' types. Mechanical contrivances have been devise for special forms and shapes and for heavy cutting. Automatic cutting machines using the oxy acetylene or oxy-coal-gas blowpipe, with or without preheated cutting oxygen, have reached a high degree of perfection. These machines usually have the full range of movements found on universal machine tool and have a degree of accuracy such that accurate gear teeth can be cut and any desired number of thousandths can be left for finishing.

The following is an abstract from a manufacturer's table of cutting data :

TABLE OF APPROXIMATE METAL-CUTTING RESULTS.

(*British Oxygen Co., Ltd.*)

Thickness of Plate.	Oxygen Pressure at Regulator Outlet.	Consumption of Oxygen per Hour.	Foot-run of Metal Cut per Hour.	Oxygen consumed per Foot-run of Cut.

14	140	900	10	85
17	160	1,350	8	150

Blowpipes can be obtained for cutting steel under water. Under-water cutting is based on the fact that the water must be forced away from the heating flame and cutting jet. Up to recently compressed air has been used for this purpose, and the latest type of under-water cutting blowpipe makes use of the products of combustion. The cooling action of the water necessitates using a heating flame five to seven times as powerful as that used for cutting the same thickness of material in the ordinary way. With an efficient arrangement an ordinary hand-cutter can be adapted for cutting under water. In salvage work steel plates have been cut at a depth of 40 ft. Various devices for lighting the flame under water when it becomes extinguished have been successfully introduced, the most recent being in the form of a pilot light burning continuously and forming part of the blowpipe.

Cast iron can be cut by means of the oxygen lance or by a special oxy-acetylene blowpipe. In the former case an iron tube from 6 to 12 feet long, $\frac{3}{8}$ in. external and $\frac{3}{16}$ in. internal diameter, containing three wires of 12 gauge, is supplied with oxygen at a pressure of from 70 to 150 pounds per square inch, according to the thickness to be cut. The point at which the cut is to be started and the end of the tube are raised to a red heat by means of an oxy-acetylene blowpipe, the oxygen turned on and the heating blowpipe removed. Combustion of the cast iron and the tube proceeds rapidly ; it takes 20 seconds to penetrate a piece of cast iron 4 inches thick and less than 2 minutes for material 24 inches thick. In the second method a cutting blowpipe with a flame having a distinct excess of acetylene is used, or a blowpipe in which the cutting jet is modified and not the heating flame. In the latter type a certain quantity of acetylene is introduced into the cutting jet and leads to an increase in the temperature of the oxygen.

The following is an abstract from a manufacturers' table of cutting data :

TABLE OF APPROXIMATE RESULTS FOR CAST IRON CUTTING.

(*British Oxygen Co., Ltd.*)

ELECTRIC WELDING.

Electric welding processes can be placed in two distinct groups, one producing heat by th resistance of the metal being welded to the passage of the current, the other using the heat the electric arc. They are known as Resistance Welding and Arc Welding, respectively. Thes two main groups have formed the basis for many processes of welding. The differences re entirely on methods and special applications. The subdivisions are as follows:

Arc Welding.

(1) Carbon or graphite electrode.
(2) Metallic electrode.
  (*a*) Bare electrode.
  (*b*) Coated electrode.
  (*c*) Covered electrode.
(3) Electric blowpipe.
(4) Atomic hydrogen.
(5) Shrouded arc.
(6) Gas shielded.

Resistance Welding.

(1) Butt welding.
  (*a*) Flash welding.
  (*b*) Upset welding.
  (*c*) Automatic butt or contact flash.
(2) Mash welding.
(3) Seam welding.
  (*a*) Butt seam welding.
  (*b*) Lap seam welding.
  (*c*) Bridge seam welding.
(4) Percussive welding.
  (*a*) Electro-static.
  (*b*) Electro-magnetic.
(5) Spot welding.
  (*a*) Lap spot welding.
  (*b*) Bridge welding.
  (*c*) Button welding.
  (*d*) Disc depression welding.
  (*e*) Point welding.
  (*f*) Multiple point welding.
  (*g*) Multiple electrode welding.
  (*h*) Ridge welding.
  (*i*) T spot welding.
  (*j*) Duplex spot welding.

The many systems of welding which have developed from these main groups are generall associated with the inventor's name or company exploiting the process, such as :

Benardos System.	Thomson System.	Quasi-Arc Process.	Ferro-Arc Process.
Slavianoff System.	Premier Electric System.	Daysohms System.	A.C. Welding System
Kjellberg System.	Alloy Welding Processes.	Cyc-Arc Process.	Fluxode System.
Zerener System.	Plactic-Arc System.		

ARC WELDING.

Commercial efficiency of arc welding processes is estimated by the relation that the qualit of the work bears to the cost. The principal factors which decide the quality of the work are (*a*) electrodes; (*b*) current (D.C. or A.C.); (*c*) welding equipment; and (*d*) efficiency of th welder. In assessing the cost the principal factors are: (*a*) capital expenditure; (*b*) depreci tion and maintenance charges; (*c*) wages; (*d*) cost of electrodes; and (*e*) cost of electrical energy The speed of welding enters into the question of cost provided increased speed is not obtaine at the expense of welding efficiency. The absolute requisites for good work are: (*a*) low voltage (*b*) a short arc; and (*c*) constant heat per unit area in the weld. An arc welding circuit shoul possess the following characteristics: (1) Ease of arc establishment when the work and electrod are cold; (2) freedom from undue tendency to freezing of electrode or extinguishing of arc wit maintenance of short arc streams; (3) stable arc with maintenance of short arc streams (4) limited current increase with growth of liquid globule; (5) limited increase of current at th instant and during the period the globule short circuits the arc stream; (6) the arc voltage shoul increase rapidly at the instant of globular detachment or on breaking a momentary short circui in order to facilitate re-establishment of a stable arc.

Carbon Arc Welding.

The characteristic principle of this process, commonly known as the Benardos process, i that an electric arc is held between the metals to be joined, which forms one electrode of th circuit, and a carbon rod or pencil manipulated by the welder which forms the other electrode By placing the carbon electrode in contact with the metal, thus closing the circuit, and instantly withdrawing it again, an electric arc is formed between the two electrodes and, owing to th high temperature of the arc, the metal is melted. Steel up to $\frac{3}{32}$ in. is satisfactorily melted togethe without using a filling material, but for greater thicknesses a 'melt bar' is melted into plac by the heat of the arc. Automatic machines for repetition work on thin materials and equippe with carbon electrodes are in use. Experience has shown that the metal to be welded shoul be the positive electrode, and the carbon the negative electrode. If this order is reversed, shorter arc is obtained and particles of carbon can enter the molten metal and cause brittleness

The current used is direct, the voltage being from 60 to 90, and the amperes vary from 25 to 600, depending upon the thickness of the metal.

The use of graphite electrodes in place of hard carbon electrodes is increasing as the merits of ıe graphite electrode are more widely known. The chief advantages are: (*a*) breakage in ıandling and in operation is appreciably reduced; (*b*) breakage and cracking due to sudden ıanges of temperature is eliminated; (*c*) less carbon is carried into the weld; (*d*) the arc is much eadier; (*e*) the life is from two to three times as long as for an amorphous carbon electrode of ıe same diameter; (*f*) electrical conductivity is four times that of the carbon electrode of the ıme cross-section, consequently the heating caused by resistance is negligible and much higher ırrent densities can be carried. Considerable development is being made in the art of carbon 'c welding where graphite electrodes are used, and an automatic graphite electrode arc welding achine has been placed on the market. The single or double graphite arc has proved useful in ıe welding of non-ferrous metals.

Metallic Arc Welding.

The use of metallic electrodes for arc welding has proved more satisfactory than the use of ırbon or graphite electrodes, which necessitate feeding the new metal into the arc by means : a rod or wire. A very wide variety of metal electrodes are used and can be classified as follows:) bare wire; (*b*) coated electrodes manufactured by dipping in, or spraying with, a liquid;) coated electrodes, which are wrapped with a refractory material or otherwise encased in a much eavier covering than that used for coatings. They can also be classified as: (*a*) heavy slag epositing electrodes; (*b*) light slag depositing electrodes; (*c*) flux-coated electrodes which de- osit no slag; and (*d*) bare wire. The effect of surface materials on electrodes from the standpoint some of the scientific laws governing the metallic arc has been investigated and it has been own that the presence of non-metallic materials on the surface is required. Generally speaking, ıere is a sphere of utility for each type, and provided care is exercised in their selection, a weld maximum efficiency should be obtained.

Bare Electrode.

The Slavianoff System, using a bare metal electrode, has not been developed in this country any extent. There is considerable discussion as to the efficiency of bare electrodes, and although may be possible to successfully weld mild steel with such electrodes, where toughness is desirable necessary, or for the welding of steel alloys, a coated or covered electrode will give better and many cases, the only successful results. The decision of Lloyd's in approving the use of covered ectrodes has not caused the adherents of the bare-metal electrode to abandon their position. he bare electrode imposes a minimum thermal load, but requires the presence in the equipment a high stabilising factor. The following is an abstract from a specification for bare iron and eel electrodes for welding mild steel, steel forgings and castings, plates, bars, etc.:

Carbon	0·06	per cent. maximum.
Manganese	0·15	,, ,,
Phosphorus	0·04	,, ,,
Sulphur	0·04	,, ,,
Silicon	0·08	,, ,,

In the hands of an experienced welder electrodes should demonstrate good weldability in flat' and 'overhead' positions, and should pass through the arc smoothly and evenly without ny unusual characteristics.

The data at hand show that bare steel electrodes having a carbon content between 0·18 and ·85 per cent. are of no particular value.

Coated and Covered Electrodes.

The use of coated and covered electrodes aims at improving the metal in the weld, permitting ıe use of alloy steels, non-ferrous metals, etc., as electrodes, facilitating electrode manipula- ion and the use of alternating current. Covered electrodes may be placed in two general classes, ıe first class being the electrode which has a heavy covering of scientifically prepared material ontaining a deoxidiser. The second class of covered electrode is of the type which has a very hin coating on the wire and aims at obtaining the same results as the heavy covered electrodes ithout manipulating the heavy coating of slag deposited during the welding operation. It is ossible to obtain as many as twenty different types of flux-covered electrodes, each specially esigned for depositing a particular material. As a result of research work, electrodes are now vailable for the purpose of welding and depositing non-ferrous metals.

Kjellberg System.

The effect of refractory coverings on the metal electrode was first discovered by Kjellberg In the Kjellberg process, controlled by the *Anglo-Swedish Electric Welding Co., Ltd.*, the stee rod is covered with a coating or sleeve of normally non-conducting materials—that is to say conductors of the second class—the junction of the cover being, amongst other things, to direc the metal where it is required, to protect the fused metal from oxidation, and to make up th loss in the arc of certain constituents of the iron or steel forming the object.

In carrying out the process the covered rod is held in a clip or holder connected to a con tinuous current supply, and forms the positive pole, the object forming the negative, though i some cases the poles are reversed.

The covering is removed from the end of the rod to enable the current to pass, and an arc struck between the rod and the object. As soon as the arc is struck a portion of the metal the object, having an area approximately equal to the section of the rod, fuses together wit metal from the end of the rod, and at the same time the covering, which is of a friable natur partly fuses and breaks away at the same rate as the metal of the rod is deposited. In this wa metal can be gradually deposited on an object until a sufficient quantity has been obtained f the purpose required. From time to time the deposited metal is hammered so as to consolida it in exactly the same way as a weld made in the fire.

A further advantage of the covering on the rod is that the tensile strength of the weld ca be varied within certain limits to suit the purpose required. For example, by this process tensile strength of from 20 to 35 tons per sq. in. can be obtained. It is possible also to obta various degrees of hardness merely by altering the composition of the covering.

'Quasi-Arc' Electrodes.

These electrodes are the special product of *The Quasi-Arc Company, Limited*, and are patent throughout the world. The company also supply special plants which enable electric arc weldi to be carried out with both A.C. and D.C. supplies of any voltage in the most economical an efficient manner.

'Quasi-Arc' Electrodes consist of a special steel wire coated with a mineral flux havi distinct physical and chemical properties whereby a weld of the highest mechanical streng and purity is obtained.

In making a weld or reinforcing a worn surface the electrode is held in an insulated hold connected by a flexible lead to the positive pole of an electric generator, and an arc stru between the electrode and the work which carries the negative connection. The welding operati is continued by holding the point of the electrode just under the surface of the molten slag a feeding down uniformly the electrode as the metal is deposited on the work.

The flux covering of the 'Quasi-Arc' Electrode has special properties to enable a low curre to be used in fusing the electrode. The fused covering is acid in reaction, automatically removi any mill scale or iron oxide from the work; it is also reducing in its chemical character, so that absorbs oxygen, and prevents atmospheric gases from causing defects in the weld metal and at t weld junction. The electrode therefore deposits a maximum possible amount of metal free fr defects with a low current consumption, so that welding is not only reliable but very economic The aluminium wire incorporated with the electrode further prevents oxidation of and remov gases from the weld metal. The low current used not only gives economy but prevents lo overheating and embrittleness in the adjacent steel of the work, so that the weak brittle zo formed in the work when using many other types of electrodes is absent.

The metallurgical principles of the 'Quasi-Arc' Electrode follow closely those used in mode steel-melting practice.

Apart from Mild Steel Electrodes, the company manufacture special electrodes for weldi Cast Iron, Carbon Steel, Manganese Steel, Stainless Steel, and Special Boiler Electrodes. T latter are a recent production, and are used for constructions which are subject to high inter pressures and for work which is stressed at a high temperature.

The following table gives the comparative strength of riveted joints and joints made w 'Quasi-Arc' Electrodes. These figures are the results of official tests carried out by Lloy Register of Shipping, and it was on the excellent results obtained that 'Quasi-Arc' Electrod were the first to be approved for welded ship construction.

ABLE SHOWING COMPARATIVE TENSILE TESTS OF LAP JOINTS OBTAINED BY RIVETING AND THOSE OBTAINED WITH 'QUASI-ARC' MILD STEEL ELECTRODES.

WELDED WITH 'QUASI-ARC' ELECTRODES.

The use of 'Quasi-Arc' Electrodes has been authorised by the British and Foreign Admiralties, Lloyd's Register of Shipping, the British Corporation for the Survey and Registry of Shipping, Det Norske Veritas, and Nederlandsche Scheepvaart-Inspectie Bureau, for use in the more important parts in ship construction.

'Quasi-Arc' Electrodes were exclusively employed in the construction of the all-welded motor ship *Caria* (ex *Fullagar*), of 400 gross tonnage. This vessel, built in 1920, has each year successfully passed Lloyd's Annual Survey, and is at present in service at British Columbia, having been recently renamed *Shean*.

Among later achievements by the use of 'Quasi-Arc' Electrodes is the application to a completely welded 3,000,000 cu. ft. gasholder, 200 ft. in diameter, 100 ft. high, with three lifts. Since this gasholder was satisfactorily completed, others have been constructed by the same method, together with the whole of the necessary framework. In addition, gasworks plant, including retort houses, condensers, gas mains, etc., have also been welded with 'Quasi-Arc' Electrodes. Hydro-Electric Pipe Lines have also been completely welded with 'Quasi-Arc' Electrodes and a number of oil storage tanks, the largest being 100 ft. in diameter.

'Quasi-Arc' Electrodes are used in all the Royal Dockyards and by the principal railway and tramway companies, collieries, mines, engineering firms, and shipyards in Great Britain and abroad.

An impact or alternating impact and bending test gives a much better measure of the quality of a weld, especially the toughness, than a tensile test. Moreover, such a test conforms more to service conditions. A 'Quasi-Arc' weld being of sound and pure metal gives a very high result under such a test, whereas a weld made with an electrode not having a special reducing flux gives a value, due to the oxide defects present in the metal, sometimes a third of that given by a 'Quasi-Arc' weld.

Note on Corrosion, in relation to Joints made with 'Quasi-Arc' Electrodes.

In view of the importance which the subject of corrosion bears to that of welding, the following notes on this matter may be added:

Fundamentally, corrosion is electrolytic in character, and depends on the difference in potential of contiguous areas.

Commercial iron and steel contain areas which in the presence of an electrolyte (which may be merely atmospheric moisture) are capable of forming voltaic circuits, the necessary condition being afforded by the presence of small defects of iron oxide, etc., or by local conditions of strain in the metal itself. These impurities or strains give rise to areas of higher electrolytic potential, and form electro-positive points which are first attacked by the corroding agent. Thus in a caulked joint, corrosion will commence at the caulking, and similarly a riveted joint will be attacked round the rivet head, owing to the local strains in the metal at these points.

In a welded joint, if the metal at the weld be less pure than the surrounding metal, the weld will be first attacked. Similarly, if the added metal be not homogeneous, local differences in potential in the weld itself will cause corrosion at the weld.

A microscopic examination of the metal deposited by 'Quasi-Arc' Electrodes shows it to be of great purity, and the usual laboratory tests show it to be always electro-negative to the surrounding metal. Hence it follows that this weld metal will have a high factor of resistance to corrosive influences.

In order that the best results may be obtained with 'Quasi-Arc' Electrodes it is essential that the electrical conditions be satisfactory. The Quasi-Arc Company have carried out a considerable amount of research work in order to determine the best designs for various types of plant. Although primarily the electrode governs the quality of work carried out by the arc welding process, it is of great importance that the plant be able to provide the correct amperage for the electrode in use, and that the arc remain stable at this current. The Quasi-Arc Company supply special D.C. generators of the drooping voltage type for single operator installations, and also constant voltage machines for multiple welder sets which fulfil these conditions in every way. These can be supplied as motor generators for A.C. or D.C. supplies or self-generating units driven by internal combustion engines.

The company have also paid particular attention to static transformer equipment for A.C. supplies, and can offer sets with which it is possible to carry out with 'Quasi-Arc' Electrode welding of quality equal to that effected with a D.C. current.

They have recently brought out a welding unit for A.C. welding of particular interest, which is known as a Compensated Rotary Transformer. This machine supplies an alternating current to the arc, and generally has the economic advantages of static transforming plant. It has, however, several additional features which render it suitable for use on supply systems where static plant is not advisable. These may be summarised as follows: (1) The load taken from a polyphase supply is perfectly balanced; (2) the power factor is of a value equal to that taken by well-designed induction motors; (3) the ease of welding operation is increased by supplying the arc with current at a frequency three times that of the frequency of supply.

All 'Quasi-Arc' plants have been designed to obtain a maximum electrical efficiency with the simplest methods of control, so that the welder can adjust his welding current without difficulty and without electrical knowledge.

Alloy Welding Processes System.

'A.W.P.' electrodes are flux-covered, and have, in general, a spiral winding of asbestos yarn as a basis of the covering. Asbestos in itself is a flux, as it fuses and combines with iron oxide forming a compound silicate, which reaction assists the operation of the flux coating. This spiral asbestos winding makes an excellent vehicle and support for the covering; which contains various valuable constituents, and is the chief feature of 'A.W.P.' electrodes. A suitable binder is used making a tough-coated and concentric sheath to the metal core. These electrodes, therefore, travel and handle without damage to the covering. They are approved by Lloyd's Register of Shipping, the British Corporation for the Survey and Registry of Shipping, and Bureau Veritas, and give equally good results on either direct or alternating current.

The chief problem in electric arc welding is to prevent as far as possible the partial combination of the molten metal with oxygen and nitrogen—in other words, to avoid the formation of metallic oxides and nitrides, as these compounds are, in general, very detrimental to the success of the welding.

By the aid of the flux covering, the molten metal is shielded from contact with the air, and is properly chosen it also serves the purpose of disposing of whatever oxides or nitrides may have unavoidably formed.

These fluxes, however, when carefully chosen not only tend to eliminate undesirable elements in the welded metal, but can be made effective in producing any desirable chemical composition in the deposited metal.

The 'A.W.P.' process has made it possible to lay down deposited metal of any predetermined composition, and to duplicate in the weld such metals as manganese steel, high-carbon steel, high speed steel, stainless steel, etc., and other steels of very special qualities, which it would be impossible to secure with an electrode having a core of alloy steel. This subject is fully dealt with in the company's bulletins, which can be obtained on application.

'A.W.P.' electrodes are made in twenty different types to suit all classes of work.

F. 2771

The growing importance of arc welding in engineering operations has caused *Alloy Welding Processes, Ltd.*, to give special attention to the design and construction of a welding generator, which besides being light in weight, and therefore easily portable, will be capable of meeting every requirement of the welder in regard to its ability to handle electrodes of any make and any size within the range at present manufactured.

The 'A.W.P.' patent welding generator is a plain shunt-wound machine without separate exciter, or reverse compound winding. It is of the drooping characteristic type, having an open circuit voltage of approximately 70, which, however, drops to the pressure required at the arc immediately welding commences.

The machine can be adjusted, by means of a shunt regulator, to suit any size of electrode at present made.

On top of the dynamo frame is fixed a casing containing an oil-immersed transformer, the primary of which is connected in series with the main circuit and the secondary connected in the shunt field circuit.

The object of this transformer is to inject voltages into the shunt winding during sudden changes of load in the main circuit. This it does so effectively that the tendency for the main current to vary is checked immediately, in consequence of which a very stable arc is obtained. With a machine of this description there is a complete absence of spluttering at the arc, and the metal deposited is homogeneous and free from holes or sponginess.

The 'A.W.P.' dynamo can be supplied direct coupled to engine-driven plants for portable use, as motor generator sets fitted with either an A.C. or D.C. motor, or arranged for belt drive.

Alloy Welding Processes have also specialised in welding with alternating current and are the proprietors of the Daysohms patent A.C. welder, which is fully described in the following paragraph.

Daysohms' System.

This system is designed to work on ordinary alternating current supply circuits, and is portable or stationary as desired. One of the advantages claimed is the special adaptability of the device for the efficient welding of very thin metal; strips of mild steel, No. 20 S.W.G., have been welded in angle form at the rate of 1 ft. in 2 mins., the current being 27 amperes at 65 volts on open circuit with a power factor of 0·45. The supply current is transformed to the necessary voltage and then passes through a choking coil. This has a straight core, with pivoted keeper which can swing, the speed of its movement being controlled by a dashpot. Limits can be set to the movement on each side by means of cam-form stops. With passage of current the keeper of course tends to be attracted towards the core, and the nearer it approaches, the lower the flow of the current, owing to the increased choking effect. The limit of the approach is set by the adjustable cam, and in this way any welding current within the limits can be obtained. The other cam, which controls the striking current, similarly regulates the distance by which the keeper can move away from the core by gravity or spring. As has been stated, the speed of the movement is controlled by the dashpot, and this can be regulated by means of a perforated disc in the piston. Consequently both striking and welding currents can be adjusted independently, and the keeper is free to move between the stops under the control of an adjustable dashpot, so that the characteristic curve connecting volts and amperes is the resultant of the two curves which would have been obtained if the keeper had been fixed in either position. The consequence is that it is possible to weld with a lower open-circuit voltage and, in addition, to weld thinner material without burning through, as the striking current can be set so as to be very little in excess of that required for the actual welding operation. In working the firm recommend that the current for welding should be adjusted first and then the striking current reduced until there is just sufficient excess to enable the arc to be struck easily.

These welding machines are available in two standard sizes, one for currents between 25 and 100 amperes with infinite gradation, and the other similarly for currents up to 200 amperes. The machine is supplied as a complete unit ready for connection to the supply main, and any ordinary flux-covered electrode can be employed.

Premier System.

The standard electrodes manufactured by the Premier Electric Welding Co., Ltd., are composed of a steel alloy of carefully controlled composition and coated externally with a thin layer of non-metallic substances. This volatile coating ensures that the molten metal is protected to a considerable extent from oxidation and nitrogenation, and the composition of the electrode itself ensures that a sound weld with good mechanical properties is produced.

The Premier system of arc welding aims at distributing the current at the required welding voltage without any mechanical control whatsoever. This is obtained by the use of a dynamo of a special type connected with the arc through a special reactance coil in the main circuit. This coil absorbs no appreciable energy, but effectively damps out any sudden rise in current, and at the same time helps momentarily to build up the current when any sudden reduction takes place.

The company manufacture a plant of the multiple operator type which does away with large and wasteful series resistances. It is claimed that as a result the power consumption of the equipment is lower than that of other multiple plants, and the method of operation is briefly as follows:

The main welding generator develops current at 35 volts and is direct coupled to a small arc striking generator which gives a small current at an additional 35 volts. By means of the special Brookhirst Contactor Gear which is fitted to this plant, a combined voltage of 70 is at all times available, for either or both welders, for the purpose of striking the arc, and, as soon as an arc is struck, the contactor gear previously referred to automatically cuts out the arc striker, and welding proceeds on the main generator.

It will thus be seen that the new plant is effective for welding at 35 volts; thus effecting considerable economy in running costs. Approximately 7½ h.p. is required per welder, this figure being slightly more in case of plants for a small number of operators and slightly less in case of plants employing six or more operators. First-class welding results are obtained without causing the slightest difficulty in striking and maintaining the arc and without any trace of interference between welders.

Ferro-Arc System.

The Ferro-Arc system employs electrodes with a coating of flux and slag-forming materials. The core metal of Ferro-Arc electrodes is of the highest quality and made to an exact specification for arc welding. The principal component of the flux is powdered blue asbestos fibre specially treated and combined with other substances which control the melting point of the asbestos and enhance its power of dissolving oxides of iron and other impurities. Blue asbestos is peculiarly suitable for use as a flux, and it is doubtful whether any other material or combination can give such successful results in arc welding.

Ferro-Arc flux fuses evenly and level with the melting of the metal core, and when molten is fluid, free, and mobile, entirely covering and protecting the deposited metal. The flux has definite deoxidising properties which, together with its powerful solvent action for oxides, ensures the deposition of clean metal free from impurities. The scavenging action of the flux removes scale and rust from the surfaces to be welded, and so results in perfect fusion and interpenetration of weld and parent metals. The necessity for a substantial coating on the electrode for the achievement of best results should be emphasised. It is not possible to deposit sound metal free from oxides and impurities and which is thoroughly united to the parts to be welded without an adequate amount of flux and slag. A substantial coating in no way hinders the operator. On the contrary it assists him greatly, improving both the speed of deposition and ease of manipulation, while ensuring the soundness of the deposit and the neatness of finish. Valuable ingredients may be imparted to the weld from the coating.

The company manufactures three grades of electrodes for the welding of mild steel, i.e. Types A, B and C, which vary in quality and price. The flux coating is in each case based on blue asbestos powder. In addition there is type AA for welding mild steel where exceptionally high strengths are required or where it is required to hot-forge the part after welding.

All the above types may be used on any standard plant using either direct or alternating current. Remarkably good results are obtained with these electrodes, the outstanding features of which are smoothness of working, penetration of the metal, neatness of finish, and high strength of the weld.

For the welding of cast iron two types of electrode are made. The standard type is specially designed to deposit a true cast iron in the weld, while Type D deposits a nickel-copper alloy which has the great advantage of forming a soft machinable deposit without preheating; with this electrode cast iron may be welded 'in the cold' without the formation of hard spots, particularly in the line of junction.

Electrodes to deposit 14 per cent. manganese steel and 0·5 per cent. and 0·8 per cent. carbon are also supplied.

A new development is an extremely successful electrode for welding stainless steel, particularly 'Staybrite.' This electrode deposits a metal containing 10 per cent. nickel and 15 per cent chromium. The composition of the electrode could be suitably altered so as to give other desired combinations of nickel and chromium. In working it is particularly smooth, fusion is perfect and neatness of finish remarkable. The deposit is very tough and entirely free from blowholes. Its resistance to corrosion is as high as that of the metal on which it is deposited. It may be used for the welding of mild steel to stainless steel.

The Ferro-Arc Welding Company's system of electric arc welding employing Ferro-Arc electrodes has been tested and approved by Lloyds Register of Shipping.

A.C. System.

The A.C. welding system is one which embodies novel features. The nature of a welding arc is such that the use of bare wire with alternating current for welding purposes is impossible unless special provision is made to counteract the effect of the periodic cessation of power.

Before the introduction of the A.C. welding system, the use of alternating current for welding purposes was condemned as inferior to D.C., and was only used in conjunction with heavy slag-forming electrodes.

A paper which was read before the Institution of Welding Engineers* explained the theory

* *Theories and Facts to Aid in the Choice of an Efficient Arc Welding System*, by D. T. Smout A.M.I.E.E

THE SIX ESSENTIALS
OF A
FIRST-CLASS ELECTRODE

THE CORE **1.** Of best quality metal, tested before use in manufacture of the electrode.

THE FLUX COATING **2.** Should form a protective sheath round the arc, preventing access of atmospheric gases.

3. Melt uniformly and evenly with the metal core.

4. Provide a stable arc giving operator steady directional control.

5. Ensure chemically clean surfaces, permitting true and complete union of metals, and should include a deoxidiser.

6. Form a freely moving fluid slag, present in sufficient quantity, and easily removed.

Ferro-Arc Electrodes

Conform in every way to the requirements set out above, which are borne in mind at every stage of manufacture.

of arc stability, and showed the difference between the A.C. welding system and the transformer and fixed reactance stabiliser, which had hitherto been in vogue. It also shows that the tendency of the arc to die out is counteracted by the method of arranging the choking effect in the circuit as a variable quantity instead of being a fixed value. The 'Alternarc' transformer of the A.C. system can be adjusted to have a certain average value for its reactance, and this governs the average value of the power supply to the arc, in the same way as a fixed reactance choke coil is designed to determine the value of the power supply to the arc. The reactance of the 'Alternarc' transformer, however, is not a fixed quantity, but varies with the current over the whole load cycle, in such a way that when the current is at minimum the reactance value is a minimum, and *vice versa*.

The effect of this method of arc control is to give very high arc stability; so high, in fact, that it is claimed possible to do equal, and even more efficient, welding work with alternating current than with direct current.

Alternating current has been condemned for welding on many occasions, owing to the fact that the arc stability factor supplied by the transformer and choke combination was so extremely low. This bad feature of poor arc stability has now been overcome by the A.C. system, and consequently, with maximum welding efficiency possible with alternating current, coupled with the desirable features of high electrical efficiency, portability, and low first cost, the A.C. welding system offers a most efficient and economical welding system.

The way in which the variable reactance control is arranged is as follows:—The 'Alternarc' transformer consists of a primary winding wound on one limb of a closed core, having two secondary windings, one of which is wound to have high mutual inductance and low leakage inductance with the primary coil, and giving a heavy leakage flux on full load. In some cases an alternative path is arranged for the leakage flux by extending the core yokes between which extensions a movable flux-diverter is arranged. Both sections of the primary windings are tapped at intervals to give adjustment to the voltage and also to the current, the movable flux-diverter giving a fine adjustment for accurate work.

The material used in the construction of the transformer is fireproof, the windings being composed of asbestos-covered wire, insulated with pure mica. Each of the larger type machines is provided with a cooling fan, and is enclosed in an oak case arranged with Sedan handles, in such a way that a whole apparatus is a portable unit.

To summarise, the claims made by the A.C. Welding Company for their system are—maximum welding efficiency, maximum arc stability (giving the choice of any electrode on the market); maximum electrical efficiency (giving minimum running cost); minimum upkeep (there being no adjustments of brushes, attention to commutators, etc.), and no maintenance charges. The machine is guaranteed against burning-out, and can only break down under wilful bad treatment.

The machines are normally supplied with an open circuit voltage ranging from 60 to 100, according to the settings of the secondary connections, but if required they are supplied with a standard 'Alternac' safety device, which limits the open circuit voltage to a maximum of 25 volts.

Electric arc cutting has been developed on the A.C. system. The system of cutting consists in the use of special cutting electrodes, which liberate free oxygen at the arc, steel being the basis of the electrodes on currents of 300 amperes, and carbon on currents from 600 to 1000 amperes.

Wilson Plastic-Arc System.

A wide and varied range of arc welding machines are manufactured on this system by *Messrs. G. D. Peters & Co., Ltd.* A special feature of all Wilson Plastic-Arc Welders is the Control Panel, which gives the machine welding qualities available in no other way. These panels, which have a range of adjustment to suit the particular welder, give close current regulation without the use of a separate exciter or brush moving. The whole equipment, which includes all accessories, is compact and built for service and can be supplied with a motor of practically any characteristics to suit the local source of power supply, or the generator can be supplied without a motor, to be driven by any means locally available, such as, for example, a belt. Alternately the unit can be petrol driven, and portable petrol sets are a speciality of the firm.

The electrodes supplied by the firm have a world-wide reputation and are known as the Wilson 'Colour-tipt' Welding Metals. The composition of each grade of metal, which covers all welding requirements, is the result of exhaustive experiments to provide an electrode having proper flowing qualities, penetration, and characteristics as deposited metal, to produce a sound, mechanical weld. The packing and marking of these electrodes has received considerable ingenuity and attention which ensures economy and their ready identification under practically all conditions of use.

Fluxode System.

The Fluxode system, Engineering Developments, Ltd., uses flux-covered and bare-wire electrodes which can be used with any arc welding plant. Mild steel, high carbon and manganese electrodes of both types suitable for high-class welding with high tensile strength or where a hard deposit, such as for reinforcing or building up tramway and railway rails, is required.

Arc welding plant to meet all conditions and for use on alternating or direct current has been designed from the point of view of economy and efficiency. The single operator set, for example, is suitable for any standard voltage on direct or alternating current supply varying from 100 to

500 volts. The set consists of an electric motor coupled to a specially wound welding generator which possesses a variable voltage characteristic similar to that obtained by the combination of a level voltage supply with a stabilising resistance in series with the arc. There is a reduction of about 50 per cent. in the cost of electrical energy as compared with a generator using a stabilising resistance. Owing to the special winding, an unskilled operator can make a much more efficient weld than with the ordinary generator.

Electric Blowpipe Welding.

In this process the electric blowpipe is essentially a horizontal-flame arc lamp using two carbons mounted like the letter V. The process was introduced by Dr. Zerener in 1890, and is usually known as the Zerener system. The flame of the arc was directed away or deflected downwards by means of an electro-magnet in series with the arc. The apparatus is bulky and complicated, and for even moderate-sized work it must be suspended from above. This method of welding eliminates the passage of the current through the work. It has not proved as successful as the methods already mentioned, and has been superseded by them. The Voltex Process is a variation of the Zerener method, in which the carbon electrodes are impregnated with metallic oxide which is vaporised by the flame of the arc.

Arc Welding Equipment.

Electric-arc welding may be done with a direct-current or alternating-current arc, having a reasonable degree of stability and sufficient amount of heat to accomplish fusion. The effect of the 'type' of current on the efficiency of metal deposition by the arc is threefold. It affects the speed of deposition, the amount of penetration or fusing of the metal, and arc stability. The design of the welding generator or transformer affects the cost of welding. The necessity for a special machine rests upon economic factors, and the differences between the various types used are those of power, cost of operation, and difference in speed of operation due to the relative stability of the arc.

The question of direct or alternating current raises many interesting points which have never been clearly determined. Good welding can be done with both direct and alternating current. Flux-covered electrodes are essential for certain types of alternating current machines, apparently because the lagging effect of the flux and slag maintains the necessary temperature during the periodical current reversals. Comparative data by independent authorities is missing, and the question of whether direct-current welding is faster or slower, whether flux-covered electrodes enable direct current to take the lead in welding speed, whether the practical losses in motor generator and resistance compare favourably or otherwise with the alternating-current system, etc., etc., are questions which are answered by contradictory claims by both parties to this controversy. However, there are advocates for both systems, and satisfactory equipment can be obtained for arc welding with direct or alternating current.

The successful application of arc welding is largely dependent upon the selection of the proper equipment. There are two systems in general use—(*a*) single operator system, where a separate machine is provided for each operator, each machine receiving its current supply from the supply circuit; (*b*) multiple operator system, where more than one operator receives current direct from the same machine, but each operator is provided with a control panel which enables him to vary the current without interfering with the other operators.

The equipment consists of a motor generator, control panel, and accessories. When using alternating current use is made of a transformer to reduce the distribution voltage to that suitable for the weld. The various types of arc-welding apparatus have been described by Major J. Caldwell in a paper presented to the Institution of Electrical Engineers on December 14, 1922.

Amongst the accessories are protective equipment and electrode holders.

Protective Equipment.

The intense glare emitted in the process of arc welding consists of a combination of invisible infra-red rays, visible light rays, and invisible ultra-violet rays, and special safety devices are required to protect the operator from their harmful effects. For light electric welding it is necessary only to protect the eyes with goggles fitted with suitable coloured glasses. Hand shields are made for medium-weight electric welding work which can be done with one hand. They serve the double purpose of protecting the eyes of the operator and also shielding the face from the heat rays and ultra-violet radiations. For heavy electric welding it is common practice to use a helmet or hood which provides protection for the eyes, head, face, and neck, and leaves the hands free. With regard to the tint of the protective glasses, a reference to the note on goggles in the section on oxy-acetylene welding will be useful. For the protection of the hands and wrists leather gloves are used. These devices are subject to modifications to meet the requirements of special work. Neighbouring workmen and operators should be protected from the dangerous rays of the electric arc.

Precautions in Arc Welding.

The precautions that should be observed in arc welding have been set forth in a memorandum issued by the Factory Department of the Home Office (Form 329, June 1921). These deal with: (*a*) hand-screen; (*b*) helmet or mask; (*c*) gloves; (*d*) aprons; (*e*) protection from hot metal; (*f*) chipping of slag. The memorandum also deals with the comparative dangers of direct and alternating currents, use of direct current, injurious effects of radiations, etc. The memorandum on the Electricity Regulations (Form 928, 1925) should also be consulted.

Automatic Arc Welding.

Depositing metal using an automatic feed for the electrode results in a materially increased rate of deposition. Machines have been developed which are capable of welding steel 0·109 ins. thick at the rate of 22 ins. per minute. This method of depositing metal is particularly advantageous on sections of uniform shape upon which a considerable amount of metal is to be deposited. Automatic welding does not eliminate the human element in welding, but does in certain cases greatly increase the speed of the process, and in other cases obtains results which are beyond the limitations of manual operation. Automatic welding with the bare metallic electrode is in more general use at present than any other method. In one type of machine the electrode is fed to the arc from a reel by means of feed rolls actuated by a 30-volt motor which is shunted across the arc when the arc is struck. Regulation of feed is maintained by two contractors which change the direction of rotation of the feed motor when the arc voltage increases or decreases above or below a certain amount. Research has proved conclusively that a faster, stronger, and more homogeneous weld can be made on material $\frac{1}{2}$ in. or more in thickness by use of a multiple arc automatic welder, depositing the metal in two or more layers, using about 350 amperes in each arc, rather than by depositing in one layer, using an excessively high amperage. A number of welding applications involve all the requirements of automatic welding except that the size or weight of the pieces to be welded prohibits convenient handling, clamping, and traversing. In such cases a semi-automatic welding machine has proved to be of great advantage. One type of machine feeds the welding wire through a flexible conduit to a welding nozzle in which the control switch for the feed motor is located. The control mechanism operates to start and stop the feed motor. The maintenance of a uniform and steady arc depends on the operator.

In the automatic carbon arc-welding machine the welding wire is placed on the work before welding. The heat of the carbon arc fuses both the wire and base metal forming the weld. Very high speeds are thus made possible.

SPEED OF WELDING IN FEET PER HOUR.

Thickness of Metal.	Hand Welding.	Semi-Automatic Welding.	Automatic Welding.
$\frac{1}{16}$	—	25 to 50	50 to 100
$\frac{1}{8}$	7 to 16	15 to 30	30 to 50
$\frac{3}{16}$	6 to 12	12 to 25	20 to 35
$\frac{1}{4}$	5 to 10	8 to 15	10 to 25
$\frac{1}{2}$	3 to 5	5 to 8	5 to 8

Arc Welding Applications.

The application of arc welding to repair and manufacturing is very extensive, but its application should be made with a full knowledge of the possibilities and limitations of the process. In the welding of iron and steel, with their great variety of physical properties, a familiarity with the wide range of conditions is necessary to meet and solve the problems presented. In welding cast iron, copper, brass, aluminium, etc., the application of arc welding should be looked upon as in the development stage where welds with physical, chemical, and mechanical properties similar to the base metal are required.

A complete investigation into the welding of cast iron is at present being carried out, and the results, as far as they have gone, demonstrate that it is possible to weld some grades of cast iron if the proper method and conditions of welding are obtained. The following points have been considered:—(1) Preparation of the parts; (2) prevention of slag inclusions; (3) suitable values of current; (4) method of deposition and its effect on the strength and hardness of the weld; (5) reversed polarity versus straight polarity; (6) effect of long versus short arc; (7) effect of speed on the softness of the weld; (8) the hard zone and its removal; (9) relative weldability of various grades of cast iron; (10) tests of electrodes. There is a great need at the present time for data on these various points.

Cost of Arc Welding.

The cost of electric arc welding with the metal electrode process depends upon several variable factors, such as: (1) the price of labour; (2) the characteristics of the arc, (*a*) arc easy to maintain, (*b*) arc difficult to maintain, (*c*) amount of heat available; (3) the cost of power; (4) the cost of electrodes; (5) supervision required, (*a*) production work, (*b*) work of a varied character; (6) interest charge on equipment.

Welding speed is fundamentally dependent upon the rate of metal deposition. This rate varies with such factors as, energy required for liquefaction of electrode material, arc stability, current density, and electrical resistance of electrode material. It has been shown that high current welding results in an increase of 100 per cent. in the speed of welding a butt joint. Butt joints in $\frac{1}{4}$-inch plate may be welded at a maximum rate of 5·3 ft. per hour when employing 175 amperes; at 10 ft. (or more) per hour when using 400 amperes.

RESISTANCE WELDING.

There is a marked distinction between the joining of metals by the two electric processes, viz., arc welding and resistance welding. In the former the heat is localised through the action of the electric arc and no pressure is applied; in the latter the heat is localised by the resistance to the flow of the current and pressure is used.

The process of resistance welding is based upon the phenomenon that a poor conductor of electric current will heat if current is forced through it, or that a good conductor will also heat if enough current is passed through it, and that the heating effect will be greater if alternating current is used than if direct current is used. Since an imperfect joint, such as the abutting ends of two pieces of metal, or the lapping of two pieces of metal which are to be welded, is a poor conductor and offers great resistance to the passage of the current, it will naturally heat and finally cause the metal to fuse and flow sufficiently to weld. In practice the operation is very rapid because comparatively large amounts of current are used.

For this type of welding a single-phase alternating current of any commercial frequency is used. The transformer in the machine will take the current from an ordinary shop circuit and reduce it to a suitable welding current.

Resistance welding is only suitable for duplicate or repetition work. In general one machine is designed for handling pieces of the same metal and for making joints for similar design. Repair jobs have been done in special cases, but it is only in rare cases that such an adaptation is attempted.

A resistance welding machine is simply a single-phase transformer having a secondary of one or two turns, the voltage required between the terminals being only five to ten volts, and the current being limited only by the size of the pieces to be handled. The transformer is built into a heavy frame which supports the clamping jaws to handle the work and mechanical devices to regulate the heat and pressure. The machine has reached a high degree of perfection, and large savings of time and labour have resulted in production work. The principle involved has been applied in the construction of a variety of machines.

By some one of the resistance welding processes, nearly all metals and alloys can now be welded. Tin is the notable exception. The cross-section of stock that it is possible to weld by the resistance process now seems to be limited only by the electric power available. Special adaptations for heating rods, bars, billets, rivets, etc., and electric brazing and soldering machines are available. Special machines for zinc tube welding, automatic spot welding, rivet heating, forging hearths, welding hollow articles, etc., etc., have been designed, and their main features have been dealt with in a paper read before the Institution of Welding Engineers.*

Butt Welding.

Electric butt welding consists in joining pieces end to end by securing complete fusion of the entire cross-section of the pieces. The pieces to be welded are placed in the clamping jaws, one of which is stationary and the other movable; enough pressure is exerted to bring the ends into contact and the current is then turned on. As soon as the welding temperature is reached the operator increases the pressure, thus forcing the pieces together, and turns off the current. Nearly all metals used commercially have been welded by this process.

Butt welding may be subdivided into three classes, namely, (1) upset welding, (2) flash welding, and (3) contact flash welding or automatic butt welding.

As regards the first subdivision, in which the weld is made by butting the cold ends of the stock to be welded and then applying the electric pressure, it is apparently being superseded for most purposes by flash welding.

Flash welding is made by applying the current before the ends are in actual contact and utilising the flash or minute arcs that play between the ends of the stock. Some advantages of flash over upset welding are (*a*) less power required, (*b*) less extrusion or upsetting, (*c*) burnt metal

* 'Resistance Welding,' by F. E. Saunders, M.I.E.E.

is thrown off, (*d*) increased production, (*e*) stronger welds. The best technique for the flash welding of tungsten steel tips to medium carbon steel shanks in the manufacture of machine cutting tools, and the serviceability of such tools as indicated by bending and service tests, has been determined.

The third subdivision, contact flash welding, is in some respects similar to percussive welding. The weld is made almost instantly by using high continuous contact pressure and heavy current, the current being cut off by automatic methods of control.

Spot Welding.

Electric spot welding consists in pressing the pieces together while passing the current through them, and localising the flow of the current so that the weld is confined to 'spots' between the electrodes, which are used to secure the pressure. The term automatic spot weld is given to a spot weld made on a welder which applies the pressure, makes and breaks the circuit all automatically.

The material to be welded is placed between copper die points supported on the ends of two arms, and the points are brought firmly together on the metal by the use of either foot or motive power. The current is then turned on. The metal, being a poor conductor, becomes heated, and when heated to a sufficient degree, pressure is applied. In the case of automatic control, the current is turned on and off and the necessary welding pressure applied automatically by controlling mechanism usually driven by a variable-speed motor. The majority of commercial metals can be spot welded, but it is essential that the metal to be welded should offer a considerable resistance to the electric current, otherwise sufficient heat cannot be generated. The technique for spot welding galvanised iron has been determined and gives very satisfactory results. The requirements for successful welds are rounded die points and twice the current and half the pressure required for ungalvanised metal of the same thickness. The spot welding of light materials guarantees a successful product and increased production. A commercial spot welder for $\frac{1}{2}$-inch plates is in use.

During the past few years considerable investigation has been carried out with regard to heavy spot welding for ships and constructional work. Large machines capable of supplying a welding current up to 100,000 amperes, and equipped to exert a pressure up to 30,000 lbs. per square inch on each spot, have been constructed. The main difficulties which have been encountered are, briefly, electrode-tip protection and the preparation of the materials to be welded. Two secondary considerations have been the separation of the electrodes and the shape of the head of the spot welder.

The following indicate the variations of spot welding:

Button and Disc-Depression Welding.

Where very thick work is to be spot welded it is often desirable to find means to localise the current and cut down the amount of pressure required. Small metal discs or buttons can be used for this purpose placed between the head of the welder and the metal to be welded. Disc-depression welding differs from button welding in that in the disc-depression method an annular depression is provided in one of the sheets, around the disc. The method makes possible the use of a comparatively light machine for welding heavy steel plate, and also the use of less power and time for making the welds.

Bridge Welding.

This method is used to join thin sheets edge to edge without overlapping and without reducing the dimensions of the pieces. The sheets are brought together in their correct position, and then thin strips or discs are spot welded across the joint.

Multiple Electrode Welding.

Time and power can frequently be saved by making several welds at once, in which case the spot welder is equipped with two or more electrodes. It is advisable to have projections on one of the pieces to be welded to assist in localising the current. Successful multiple welding requires a separate transformer for each weld.

T Spot Welding.

When pieces are welded in the form of a **T** by holding one piece in a hollow electrode and welding it to the other the resulting weld is called a **T** spot weld.

Point or Projection Welding.

In this method the metal to be welded is provided with points or projections. The points are brought in line with each other, and the welding effect is to provide a smaller contact point which increases the resistance and allows the weld to be made with the consumption of less time and power. Ridge welding is the same as point welding, except that, instead of a single point, a ridge is raised in the metals in such a way that the ridges on the two pieces come together in the form of a cross.

Duplex Spot Welding.

In this type of spot welding two transformers are used simultaneously on opposite sides of the sheets to be welded and their currents pass through two secondaries, welding two spots simultaneously.

Combinations of all the above processes have been made for special jobs. Sometimes it is only necessary to make a change in the construction of the electrodes to make a machine do work of a varied character.

Seam or Line Welding

consists in joining pieces along a continuous line or seam, usually by moving the joint in the path of the current, so that fusion is secured continuously. The process combines the features of butt and spot welding. Machinery has been developed very successfully, but is limited to work on light stock and short seams. Standard seam welders are usually equipped with two electrodes, one connected to the work and the other a roller running over the seam, or both electrodes may be converging rollers, with the converging edges resting on opposite parts of the work near the edge to be welded. The work is passed beneath the rollers, which carry the current into the metal, and makes a continuous line of welding. The work must be carefully cleaned and be securely held by the machine to get good results. The width and strength of the weld depend upon the current, pressure, and speed adjustments as well as upon the size and character of the electrodes and the shape, size, and character of the metal being welded.

Considerable development work has been done during the past two years. It has been applied to the manufacture of steel barrels, casks, tanks, ventilators, heating and ventilating pipes, etc. Seams can be made at a rate of 40 ft. per minute on $\frac{1}{16}$ in. sheets, and 20 ft. per minute on $\frac{1}{8}$ in. sheets. The welds may be butt, lap, or bridge, and be made continuously or progressively.

Mash Welding.

Mash welding is a process of welding rods, wires, strips, etc., by crossing or overlapping the pieces and welding between relatively large electrode surfaces under pressure.

Electro-percussive Welding.

This is a process which is chiefly intended for manufacturing applications in which large quantities of duplicate parts are to be produced. The underlying principles utilised in percussive welding were discovered in 1905 by Mr. J. Chubb, of the Westinghouse Company. Following his original experiments, machines were developed for welding metals in wire form of rather small cross-section. Widely different physical properties offered no obstacle, and ductile welds can be made with copper and aluminium, platinum and lead. Electrical devices are used whereby a rapid small separation of the parts to be welded causes an intense arc to melt the surfaces. At the proper moment a forging hammer forges the pieces together. The advantages claimed for the processes are (*a*) power saved; (*b*) time of welding negligible; (*c*) welds of unequal sections are possible; (*d*) welds of unlike metals can be made; (*e*) uniform welds; (*f*) cost of finishing welds reduced. Recent results have shown that percussive welding has many valuable applications, especially in non-ferrous and steel-alloy welding.

Experimental work has been directed toward extension of the process to larger cross-sections. A large impulse transformer has been built capable of storing 20,000 joules. Sections up to $\frac{3}{4}$ in. diameter have been successfully welded and no apparent limitations are anticipated from a process point of view.

ELECTRIC CUTTING.

Although cutting with a blowpipe has many advantages over electric arc cutting, yet there are many places where the electric arc can be used advantageously. The groove is not so narrow as that cut with a blowpipe, nor is the surface cut as clean.

The electric arc will cut any metal, ferrous or non-ferrous, and has been found particularly useful for the cutting of cast iron. The thickness that can be economically cut by the arc varies from 4 to 6 inches, for straight cutting. The current necessary for cutting operations on general and heavy cutting varies from 800 to 1,200 amperes. The voltage of the cutting arc varies between 25 and 45, a good average being 37.

It will be seen that heavy values of current are required, and special apparatus has been designed so that the arc could be controlled with these heavy currents. An important part of these developments is the design of a handle to protect the operator, hold the electrode, and to carry 1,000 amperes. A small item like the use of pure graphite instead of carbon for electrode means the difference between success and failure.

Increase of current means larger electrodes and hence more metal to be cut out. The latest development for this work is a low resistance graphite electrode and the approximate sizes for various current densities are as follows:—200 amperes, $\frac{1}{4}$ to $\frac{3}{8}$ in. electrodes; 300 to 400 amperes, $\frac{3}{8}$ to $\frac{1}{2}$ in. electrodes; 400 to 600 amperes, $\frac{1}{2}$ to $\frac{5}{8}$ in.; 600 to 800 amperes, $\frac{5}{8}$ to $\frac{3}{4}$ in; 800 to 1,200 amperes, $\frac{5}{8}$ to 1 in. electrodes.

Cutting on heavy sections is generally best accomplished from the underneath side or from a vertical face tipped slightly greater than 90 degrees so that the molten metal can flow away, although the action is not entirely simply melting metal. In cutting with the arc a reasonably smooth surface can be obtained by paying attention to one side only, or the cut may be made rough and trimmed up smooth by a second application of the arc.

Recent developments consist of a special electrode for cutting with the arc, and for such work as piercing holes. This special electrode, covered with a coating giving off free oxygen under the temperature of the arc, gasifies the entire metal melted, so that the boring action is uninterrupted after once started. This electrode is used by starting the arc and immediately pushing the electrode into the puddle. After the hole is through the piece it can be widened to any size or shape by drawing the arc around its edges. This type of electrode only takes from 250 to 350 amperes. A development in under-water cutting is an adaptation of the carbon electrode arc cutting process, in which the carbon electrode is pierced by two small brass tubes, through which a special cutting gas is supplied from the surface. The gas oxidises and blows away the metal melted by the arc, and also converts the surrounding water into steam, thus making a gaseous envelope for the arc. The combined action serves to greatly speed up the operation of the cutting electrode, as the metal is blown aside before it has a chance to solidify. This device has been used successfully for cutting metal between three and four inches thick at a depth of about 70 ft.

THERMIT WELDING

Thermit is a trade name for a mixture of finely divided aluminium and iron oxide, which when ignited reacts to produce a superheated liquid steel at 5000° F. The underlying principle of the process is the high chemical affinity of aluminium for oxygen. Up to a temperature of 2800° F. thermit is an inert mixture. At that temperature the aluminium unites with the oxygen of the iron oxide and comes down as liquid steel at about twice the temperature of ordinary molten steel. If steel at this high temperature is poured around the sections to be united, especially if the sections have previously been preheated, it will melt them and amalgamate with them so as to form a fusion weld.

Four varieties of thermit are produced for welding ferrous material, *i.e.* plain, cast iron, railroad and wabbler thermit.

In making a thermit weld, the parts to be united are first lined up with a space between the ends, the extent of which depends upon the size of the sections to be welded. The ends are thoroughly cleaned and a wax pattern is formed around them, the exact shape of the reinforcement of thermit steel which is to be cast at that point to make the weld. A sand box is next rammed around the pattern and inside a sheet iron box, provision being made for pouring gates, heating gates, and risers. The parts to be united are brought to a good red heat by suitable means, such as compressed air liquid fuel. The charge of thermit is placed in a conical shaped crucible supported over the pouring gate of the mould and ignited by means of an ignition powder. In 25 to 35 seconds the reaction is completed and the crucible tapped. The slag does not enter the mould.

The process is extensively employed for locomotive repairs, marine repairs, crankshaft repairs, steel mill repairs, pipe welding, rail welding, and miscellaneous heavy welding. Detailed instructions are available for carrying out thermit welds in the fields mentioned. The process is adapted to all sizes and weights of pipe up to 6 in. diam., and an important feature possessed by the thermit pipe welding process is the ease with which it can be applied to the welding of coils. The joints can be welded either before or after the pipes are bent.

ATOMIC HYDROGEN WELDING.

Equipment has now been placed on the market for atomic hydrogen welding. The process consists in passing a stream of hydrogen gas through the arc formed between two electrodes. The heat of the arc breaks up the hydrogen molecules into atoms, and these combine again a short distance beyond the arc, and in so doing liberate a large amount of heat. Since atomic hydrogen is a powerful reducing agent, it reduces any oxides which may form on the surface of the metal and metals can be melted without the slightest trace of oxidation.

The equipment represents the results of continuous experiment, research, and trials over a considerable period. The outfit consists of a single-phase transformer for converting the voltage of a 60-cycle supply to one suitable for the welding equipment, a specially designed variable reactor for providing the proper welding current and voltage, and a welding blowpipe by means of which the actual work of welding is performed.

The blowpipe consists of a holder supporting two tungsten wire electrodes, the electric conductors connecting these to the reactor, and the tubing for the hydrogen gas. Each electrode is supported inside a nozzle through which the hydrogen is forced out around the electrode. The combination of electrodes and nozzles is set at an angle, and the distance between the electrodes, or arc length, and also the flow of gas, are readily adjustable. In contrast to the usual method of arc welding, there is no current flowing from the electrodes to the work to be welded ; the circuit is completed from one electrode to the other. When welding ceases, the welding circuit is automatically interrupted until the operator is ready to weld again, when the circuit is automatically restored.

In making welds the metal is melted under the heat of the arc, but to add additional metal a welding wire or rod must be used and fed into the arc in much the same way as that followed in oxy-acetylene welding.

The reactor consists of a U-shaped core provided between with pole faces, between which a pivoted armature can move. The legs of the core are provided with coils connected in series with the electrodes of the blowpipe. The amount of welding current and voltage is governed by the movable armature which changes the air gap of the magnetic circuit and therefore the reactance.

The new equipment is so far made for operating from 60-cycle, single-phase circuits only, and for use on ordinary metals less than $\frac{1}{4}$ inch in thickness, or on hitherto unweldable metals of greater thickness. Extremely thin material can be welded. The process is particularly adaptable to the welding of metals and alloys so far not weldable by other methods.

SECTION XLI

EXPLOSIVES.

(Contributed by Professor W. R. Hodgkinson, F.R.S. (Edin.), Ph.D., F.I.C., C.B.E.)

Explosives may be classified into 'Propellants,' which are required to produce a rapid but steady rise in pressure in some kind of firearm; others may be termed 'Detonators,' or the less definite term 'High Explosive.' The latter are practically instantaneous in action and produce a wave or vibration of high velocity. Under certain conditions some substances may behave as belonging to either class.

The first propellant, 'Black Powder,' has since 1770 (about) consisted of nitre 75 per cent., charcoal 15 per cent., and sulphur 10 per cent. Practically all the gases, which may be 700 times the volume of the powder, arise from the nitre, the volume varying according to the density of the powder and to the conditions at burning.

Gunpowders do not detonate, but may give a very rapid rise of pressure if burnt in a closed space. Being porous, though dense, the first formed and very hot gases are driven through the remainder of the charge, igniting it *en masse*.

Cordite.

Cordites and the like are practically the most satisfactory propellants invented; owing to their gelatine-like structure they are non-pervious to gases. All true colloids show this property in some degree; the rate of burning can therefore be well regulated by the area of surface, volume of gas, and temperature. Owing to their composition, these explosives are practically smokeless. The cold-gas volume (i.e. volume at ordinary temperature) is in the region of 1,000 times that of the powder, and the temperature seldom less than 2,000° C., and may be above 3,000° C., according to composition. 'Cordite' proper consists of gelatinised high grade gun-cotton with a certain amount of nitroglycerine and a mineral jelly incorporated while the gelatinising agent is still present, the agent eventually drying off. A number of varieties of these powders are made with lower grades of gun-cotton, their physical properties being much the same. These powders are not easily detonated and are useless for blasting purposes.

Gun-cotton.

Gun-cotton' and 'Cellulose Nitrates' are made by the action of a cool mixture of nitric and sulphuric acids on cleaned cotton waste or the like. Strength of acids, temperature, and time of contact determine the extent and nature of nitration. Real gun-cotton contains about 13·8 per cent. of nitrogen, nearly corresponding to $C_6H_7O_2(NO_3)_3$.

Varieties of nitrated cellulose containing 10 to 11 per cent., or less, nitric-nitrogen than real gun-cotton are also used in some classes of propellants.

Gun-cotton is unaffected by water and does not burn if containing about 10 per cent. of moisture. When dry it ignites at between 160° and 180° C. It burns without smoke and is easily detonated by a sharp blow on a hard surface. When wet it can only be detonated by a primer of dry gun-cotton. When pulped and pressed into slabs, gun-cotton (13·8 per cent. N.) is used for blasting; its action is very local.

Nitroglycerine.

Nitroglycerine is formed by the action of mixed nitric and sulphuric acids on glycerine at a low temperature. It is a colourless oily liquid of sp. gr. 1·6. It freezes easily, and melts at 4° C. It is practically insoluble in, and unaffected by, water. Solid or liquid, it is easily detonated by percussion or by heating to about 150° C., hence the danger of thawing the solid nitroglycerine. As a liquid it is unpractical as an explosive, but when mechanically absorbed into a porous inert material, or incorporated in the substance of a jelly, useful preparations result.

Dynamite.

'Dynamites' which fulfil most of the requirements for blasting, and are reasonably safe, consist of nitroglycerine incorporated in kieselguhr, cork charcoal, and the like non-gritty powders. Generally some metallic nitrate, colouring or binding dope is added. Dynamites can be detonated by fulminate detonators. They are comparatively safe to handle and store for a moderate time in a place of medium temperature. Water may cause the extrusion of nitroglycerine from most forms of dynamite.

Gelignite.

'Gelignites' are mainly a thin jelly of a low grade gun-cotton in nitroglycerine; warm nitroglycerine is usually the gelatinising agent, but others may be employed. They may contain about 90 per cent. nitroglycerine. They are plastic, waterproof, and more powerful and convenient than ordinary dynamites. They should be stored in a place of cool even temperature. Most of the gelignites are doped, for some real or imaginary object.

Permitted Explosives.

'Permitted Explosives' for use in mines are such that comply more or less perfectly to certain tests, such as non-ignition of fire damp or coal dust, not producing a dangerous amount of poisonous fumes, considerable range of safety in storage and use. In many of these explosives, ammonia nitrate is the main oxygen carrier, the combustibles being benzene derivatives such as nitrobenzene, nitronaphthalene, and the like, with or without wood meal or inert powders to cool the flash.

Perchlorate of ammonia is the chief active material in some blasting compositions for civil or military use (cheddites). They are useful in fiery mines, as a quantity of hydrochloric acid gas is produced on explosion which acts as a damper of flame. Almost any kind of organic matters may be used in this class. Paraffin wax is often used, as, amongst other properties, it is waterproof.

Perchlorate compositions are stable and keep well, but all are liable to explode on moderately strong percussion. Generally they simply burn violently on ignition by a flame.

Ordinary chlorate compositions should be completely barred, as they are never safe and are erratic in use.

Detonators.

Detonators are substances employed to start the disruptive explosion or detonation of other compounds which alone may not explode by a flame or a moderately hard blow. Owing to the extreme rapidity of their explosion, detonators initiate a molecular decomposition of the main explosive, or it responds to the wave blow of the detonator.

Mercury fulminate, $HgN_2C_2O_2$, is the oldest and most commonly used detonator. It may be used alone or diluted with nitre, antimony sulphide, potassium chlorate, or even inert substances in some proportion, in order to regulate its sensitiveness, or reduce or modify the manner of exploding.

Cap and igniting compositions contain same proportion of $KNO_3Sb_2S_3$ and $KClO_3$.

Small quantities of fulminate, say 2 grams, may flash off if fired open, but the flimsiest cover will cause it to detonate on firing by a flame contact. A very slight suddenly applied pressure causes detonation. Its function in cap compositions is to respond to the blow of the hammer and ignite the other ingredients.

Lead azide, PbN_6, acts similarly to fulminate, is stronger and quicker in action, but probably not so amenable to regulation as fulminate.

Fuses.

These are, generally, some arrangement for firing an explosive at a desired moment. They consist, as a rule, of finely ground black powder contained in a paper tube protected by tape, machine-wound over it and waterproofed by some resinous or pitchy composition. Rate of burning may be controlled by fineness of powder, and in some cases by its composition, diameter of tube, etc.

In military fuses the powder has to burn along a circuitous route of determinable length in a metal container.

Fuses for blasting are packed in barrels and cases containing 300 or 500 coils of 24 ft. length. The average rate of burning of safety fuses is 75 to 90 secs. per yard. (See also 'Trinitrotoluene.') The fuse end is inserted in the detonator cap, which is then secured in proper contact with the explosive cartridge or charge, which may be tamped in the bore hole or not according to nature of explosive. (See also 'Blasting,' page 2570.)

Lyddite, or Picric Acid.

Lyddite, or picric acid, $C_6H_2OH(NO_2)_3$, is mainly a military explosive. It is somewhat difficult to detonate, otherwise there is no reason against its use for rock blasting. When some quantity is burnt there is a liability for it to pass into the detonation stage. The chief danger in connection with it is the liability to form metallic compounds (picrates), which are extremely sensitive to heat, friction, or percussion. There are several related substances with similar properties and uses, such as dinitrophenol, nitrocresols, etc.

Trinitrotoluene.

Trinitrotoluene (T.N.T.) and trinitroxylene (and other stages of nitration of toluene, xylene, etc.) are mainly military explosives, but T.N.T. has been used for some time in instantaneous fuses for civil work. Under proper conditions all these substances could be used for blasting.

Amatols.

Amatols (of various catagories) are essentially ammonia nitrate compositions with T.N.T. and similar substances. The violence of their explosion is increased by the addition of small quantities of powdered aluminium, magnesium, and other substances.

Amatols have a great future as blasting agents, but some of them are very sensitive and are not quite waterproof.

Blasting Machines.

Dynamo Electrical Blasting Machines are specially built to explode all blasting charges with absolute safety, either in stone quarries, coal mines, or oil shale workings. Being water and damp proof they are always ready for action.

SECTION XLII

PAINTING — VARNISHES — METAL LACQUERS AND BRONZES — LUBRICANTS AND OILS — CLEANING-COMPOSITIONS — MISCELLANEOUS.

(All Parts by Weight unless otherwise Specified.)

PAINTING.

Painting Woodwork.

A mixture of linseed oil and white lead is the best preservative of wood. The linseed is the preservative; the white lead gives body and opacity. Spirits of turpentine is added as a solvent, to enable the paint to penetrate into the pores of the material; the solvent should be light and easily evaporated.

Boiled linseed oil dries quicker than raw, but is darker and thicker than the latter.

To Remove Oil Paint.

2 lbs. washing soda, 2 lbs. quicklime, mixed to consistence of cream, spread on, and kept moist for an hour. The paint can then be washed off.

Glazier's Putty.

Whiting and raw linseed oil, well beaten up.

To Remove Old Putty.

Paint it with nitric or hydrochloric acid, and after about an hour it will be soft enough to remove; or a hot iron will soften it at once.

Painting.

In painting woodwork for the first time, kill knots with coating of fresh slaked lime; then in 24 hours scrape off, and paint knots with mixture of red and white lead and linseed oil; or use red-lead powder mixed with strong glue-size, and apply warm—the work can then be gone on with in a few minutes; when dry, smooth with pumice stone. Next put on priming coat. All holes are then stopped with glazier's putty, and the required coats added; each coat in good work is rubbed smooth with glass-paper before adding another.

Painting required to have no gloss has an additional coat, made with turpentine only, and no oil, called a *flatting coat*.

For old work, if much soiled, wash with soap and water and scour; if foul with smoke and grease, wash with lime and water; then commence with *second* coat.

New woodwork should have 4 coats; for periodical repainting 2 are sufficient.

Priming.

This generally consists of a mixture of white lead and red lead, irrespective of the colour to be used in finishing. The lead mixture is diluted with boiled linseed oil and a small quantity of turpentine. A special asbestos priming for painting fibro cement and all classes of asbestos sheeting is supplied by *Messrs. Walter Carson & Sons*, Grove Works, Battersea, London, S.W. 11.

'Muraprime.'

This priming (*Walter Carson & Sons*) is for use on porous plaster walls, for walls with unequal absorption, and for walls stopped with various plasters. Internal walls on which a perfect surface is desired should receive a coat of 'Muraprime' on the bare plaster. It assists to bind loose particles, and stops unequal absorption, which often makes flat painting or distempering patchy and unequal in colour. It is sold in four colours—white, yellow, green, and pink.

'COVERINE.'

This paint (*Walter Carson & Sons*, Grove Works, Battersea, London, S.W. 11) is a white undercoating, which saves time in the preparation of undercoats. It is ready for use in five minutes, and requires to be thinned with turpentine only. One coat is equal to two coats of white lead paint, and is consequently a saving of time and material. It dries hard, and can be coated in a few hours. The finishing coat can be applied and the work completed in one day. It forms a good undercoating for gilding, and will stand washing.

'MURALINE.'

This is a washable water paint (*Walter Carson & Sons*), and is sold in dry powder, in forty artistic shades. Water added to the powder in an equal proportion makes a sanitary washable paint, which forms a highly perfect and durable surface. Compared with paste distempers (which contain about one-third of water), it is claimed to effect a considerable saving, owing to its great covering power. 1 cwt. covers 600 to 700 square yards on non-porous surfaces. It will never deteriorate if stocked in a dry place, unexposed to the air. 1 cwt. of powder with 1 cwt. of water makes 2 cwt. of paint. It can be applied to new lime plaster, if dry, without injury to the colours. It works and flows evenly under the brush, and leaves a hard, smooth surface. Intermediate shades may be produced by mixing colours or by reducing with white. It is non-poisonous and an excellent disinfectant. The colours are fast to light, and do not discolour. It does not rub off, scale, or flake. The white is an excellent covering for ceilings. Unlike whitewash, removal is unnecessary before repainting if in sound condition.

Painting Ironwork.*

For new ironwork, 3 coats Torbay or other oxide of iron paint answers well; 1 lb. mixed with oil will cover from 8 to 12 yards. For periodical painting, 2 coats. For the first, or first and second coats on iron, red lead is very generally used; 1 lb. mixed with oil will cover about 5½ yards.

'FERRI-SILICON.'

This paint (*Walter Carson & Sons*), which can be made in any colour, is a cheap and durable preservative for ironwork, woodwork, and all exposed surfaces. It is a combination of iron and other oxides with silicates, which, when incorporated with a special enamel oil, produces a paint closely resembling enamel, but with a very tough and elastic surface, absolutely impenetrable. The manufacturing process which the enamel oil undergoes is claimed to render it at least twice as durable as the finest linseed oil. The paint is specially suitable for use on gasometers, as the colours are not affected by contact with sulphuretted hydrogen gas, sulphide of ammonia, etc.

'ANTI-CORROSION.'

This paint (*Walter Carson & Sons*) is for out-door work as a preservative for iron, wood, stone, brick, compo, etc. It is employed by many of the leading railways both at home and abroad, and also on life-boat stations. It is well adapted for coating the roofs of corrugated iron buildings, etc., and is especially recommended for buildings exposed to the corrosive action of sea air as it does not blister and wash off under these trying conditions.

SYRONITE ANTI-RUST PAINT.

Syronite is a thin transparent syrup which can be painted upon new ironwork before, during, or after erection, or upon existing structures that are already rusting. If the structure is in a bad state before the Syronite treatment is undertaken, the surface is first well brushed with a stiff wire brush to remove all loose rust. A coat of Syronite is then applied, its action being to penetrate through any remaining rust and cause this to shed off. When shedding has taken place, another coat is applied, and then the treatment is complete.

Pigments can be combined with Syronite when required.

A peculiar feature of the material is its capacity of 'creeping' or spreading. Ordinary paint stays exactly where the brush leaves it, and as the brush cannot always get under and along joints, round rivets, etc., these parts do not get equal protection with the general surface.

CARSON'S ENGINEERS' PAINTS

ANTI-CORROSION

The most durable paint for Bridges and all exposed constructional ironwork.

FERRI-SILICON

A specially manufactured preservative for use on Gasometers, etc.,

Unaffected by Sulphuretted Hydrogen Gas and Sulphide of Ammonia.

QUICK-DRYING ENGINEERS'

A good preservative, specially suitable for use in Foundries, Collieries, etc. Dries hard in from two to three hours.

"MURAPRIME"

The best preservative for every kind of stone and brick work. Also for use under "Muraline" and all Distempers and Water Paints.

We are always pleased to answer queries and offer advice P.T.O.

F. 2788

CARSON'S PURE PAINTS

DISTEMPERS, ENAMELS and VARNISHES.

"MURALINE"

THE PERFECT WATER PAINT
Sanitary, Artistic, and Durable.
Requires only the addition of water to make ready for use.

"VITROLITE"

A Decorative White Paint.

Superior to white lead in colour, covering power and durability. Specially suitable for glasshouses.

The Celebrated White Undercoating.

One coat transforms back into white. Ready for use in five minutes. Can be second coated in a few hours.

PURE

LIQUID PAINT

Non-Poisonous. Ready for Use.

Specially manufactured for the finest exterior and interior decoration in over 50 countries.

Patterns and full particulars on application.

Telephone—BATTERSEA 1630 (2 lines).

Preservative for Ironwork.

(1.)

Coal-tar boiled till the watery vapour and naphtha are expelled, and mixed when cold with ¼ pint of naphtha and the same amount of boiled oil to each gallon of tar.

(2.)

Experiments carried out by the Military Engineering Department at Brest have shown that as an effective preservative for metal work coal tar is rendered far more efficient by the addition of a small quantity of quicklime, in the proportion of one part of lime to two parts of tar. The mixture, after being heated to the boiling point, is brushed upon the ironwork at a temperature of about 120° F. The tar should be used over a coating of red lead.

(3.)

A valuable rust-inhibitive coating for general priming or finishing work may be prepared from sublimed blue lead. Two parts of blue lead and one part of linseed oil containing about 5 per cent. of turpentine drier make a paint of the right consistency. When this paint is used for top-coat work in marine exposures—battleship gray—the addition of 1 per cent. of carbon black to the blue lead aids in the maintenance of the colour.

Rust Proof Coating for Iron or Steel.

Linseed oil, 25 parts; calcium resinate, 36 parts; manganese borate, ½ part; lead acetate, 1 part; naphtha, 37½ parts; artificial graphite, 25 parts. These are mixed and applied to the metal by brushing, or dipping, or any other method. The article is then baked at 300° F. for 1 hour and 40 minutes. The coating is highly lustrous and resistant to corrosion.—*American Machinist.*

Note on Iron-work Painting.

According to experiments published in the *Bulletin de la Société des Ingenieurs Civils de France*, a number of coats of paint form a much less effective rust preventive for metal than a single layer does. Iron plates well cleaned and polished were coated, some with one coat and some with two, three, or more coats of paint, and then exposed to the action of steam for a whole day, after which the paint was removed and the plates were examined. The first was as bright as it was before exposure to steam, the second showed a few rust spots, the third was still more attacked, and the fourth entirely so. This result is stated to be due to the fact that the deeper layers dry badly and tend to dissolve the uppermost coating, increasing its porosity to air and moisture.

Painting Zinc.

Dissolve 1 part chloride of copper, 1 nitrate of copper, and 1 sal ammoniac, in 64 of water, and add 1 part commercial hydrochloric acid. Paint the zinc with this, and leave to dry for 24 hours. Any oil colour will then firmly adhere to it.

To Paint in Imitation of Ground Glass.

White lead, 4 parts; boiled oil, 3 parts; spirits of turpentine, 1 part; add a small quantity of dryers. The colour must be exceedingly thin, and put on the panes of glass with a large brush in as even a manner as possible. Dab the paint over lightly with a pad of cotton-wool covered with an old linen rag.

Hydraulic Cement Paint.

Hydraulic cement mixed with oil forms an incombustible and waterproof paint for roofs of buildings, outhouses, etc.

Outside Whitewash.

Slaked lime, ½ bushel. Add common salt, 1 lb.; sulphate of zinc, ½ lb.; sweet milk, 1 gallon.

Flexible Paint.

Used for painting on canvas. 2½ lbs. good yellow soap dissolved in 1½ gallon boiling water; grind the hot solution with 3½ gallons of good oil paint.

Red Paint, quick drying (8 to 20 Minutes).

(Used for Pillar-boxes.)

Japanner's gold size	40 per cent.
Red lead	60 ,,

When dry, varnish with outside oak varnish.

Waterproof Paints.*

For General Purposes.

(1.)

2 gallons linseed oil, boiled with 11 ozs. each of rosin and litharge, 1½ oz. each of minium and umber; add gradually 8 ozs. of sulphate of zinc and a solution of 12 ozs. of potassium hydrate and a like quantity of alum in 4 gallons of water. For preparing the ground colour, compound 10 lbs. of chalk and 2 lbs. of zinc white with ¾ gallon of water in which 1½ oz. of alum has been previously dissolved, and mix with this a solution of 1½ lb. of glue in ½ gallon of water. This ground paint is mixed with 4 to 5 lbs. of the above composition, and the mixture diluted with petroleum.

(2.)

12 ozs. of melted rosin, thoroughly mixed with 6 gallons of fish oil and 1 lb. of melted sulphur and some ochre or any other colouring substance rubbed up with linseed oil. Apply several coats of the hot composition with a brush. The first coat should be very thin. Suitable for either wood or stone.

For Casks and Waterspouts.

Boiled oil, 1 part; charcoal, finely powdered, 1 part. Mix to consistence of paint.

For Vessels and Submarine Works.

Sulphate of copper, 400 lbs.; grape sugar, 100 lbs.; concentrated solution of potash, 200 lbs. The precipitate of hydrated oxide of copper formed by heating this mixture is filtered, dried, and mixed with 8 lbs. of 75 per cent. carbolic acid. Heat the mass moderately, and add about 12 gallons of crude linseed oil. When the paint is to be used it is reduced with linseed oil, and then applied. This composition is claimed to prevent the deposition of marine animals on the surface to which it is applied.

Paints for Waterproofing Outside Walls.

(1.)

Rosin, 4½ ozs.; litharge, 3 ozs., boiled in 1 pint of clear linseed oil until the wooden spatula used for stirring becomes brown. Give the walls 2 or 3 coats of this, preferably on a hot and dry summer's day.

(2.)

A solution of paraffin wax in heavy coal-tar oil is excellent for painting houses, and especially walls exposed to the action of the weather. Several experiments in painting damp walls with this solution have given very satisfactory results. Wall-paper which formerly became moist and detached from the walls during rainy weather remained perfectly dry after the wall had been painted with this solution, which is prepared by dissolving 1 part of paraffin wax in 2 to 3 parts of coal-tar oil at a moderate heat. A sufficient quantity of oil must be used so that the solution does not entirely congeal on cooling. To heat the paint while applying it, place the vessel containing it in hot water. It is best to apply the solution on a warm day, when the bricks are dry. Generally 1 coat is sufficient, but even if 2 coats are given the cost is considerably less than that of oil paint.

Paint for Wooden Floors.

Soak 2 ozs. good light-coloured glue in cold water for 12 hours, and dissolve it with constant stirring in thick milk of lime (prepared from 1 lb. of caustic lime) heated to the boiling-point. Stir in 8¾ ozs. linseed oil. Mix with any colour not affected by lime, and dilute with water if necessary. For yellow-brown or brown-red colours, boil in the ground colour ⅛th of its volume of a solution of shellac and borax. A coat of varnish produces a bright surface.

Paint for Red Brick Floors.

Wash the bricks with soap-water containing $\frac{1}{20}$th part of carbonate of soda. Dissolve 1 part of glue in 16 of boiling water and 4 parts of red ochre, and stir the mass thoroughly together. Apply 2 coats of this to the bricks, and then give a coat of linseed oil varnish.

---

* It has been proved that no paint film, of which linseed oil is one of the chief constituents, can be made *thoroughly* impervious to moisture.

Preservative Solution for Stonework.

1 part white shellac, dissolved in 8 parts wood spirit. Apply to surface by means of a watering pot provided with a rose.

Paint for Roofs.

Pulverised slate (argillaceous schist), 35 parts; pulverised mica slate (mica schist), 30 parts; pulverised rosin, 35 parts; mix with ½ its volume of pure coal-tar, and boil to a fluid mass. This paint gives a very durable and pliant coating, which does not melt in the greatest heat of summer nor crack or break in the greatest cold. It resists moisture, and retains its lustre and smooth surface. It will last for 4 or 5 years.

Paints for Preserving Wooden Posts.

(1.)

50 parts rosin, 40 parts powdered chalk, 4 parts linseed oil; melt together in an iron boiler, add 1 part of natural cupric oxide, and stir very carefully into the mixture 1 part of sulphuric acid. Apply with a stiff brush. When dry the mass forms a coating as hard as stone.

(2.)

1½ part rosin (melted), 48 parts fish oil, 1½ part sulphur. When the mixture is thoroughly combined and liquid, add sufficient ochre rubbed up with linseed oil to give the desired shade of colour. Apply the mass while still warm in as thin a coat as possible, and in a few days, when the first coat is dry, repeat the operation.

Paint for Felt Roofing.

Washed graphite, 2 parts; red ochre, 2 parts; cement, 16 parts; barium sulphate, 16 parts, plumbic oxide, 6 parts. These materials to be ground in an oil varnish prepared as follows: 100 parts of good linseed oil are boiled for 8 hours in a copper boiler with 5 per cent. of pyrolusite. 10 parts of flowers of sulphur and 20 parts of French pitch are then dissolved in the mixture, and the mass filtered before it becomes cold. 25 lbs. of this composition and 1½ gallons of linseed oil varnish or linseed oil, for reducing the paint, are sufficient to give 2 coats to 1,000 square feet of roof surface. The first coat, while still wet, is uniformly covered with fine dry sand by means of a sieve. The sanding should be done during the progress of the painting, so that the workman is not obliged to step on to the wet paint. The free sand is renewed with a broom before the second coat is given, and it is best to apply this 8 days after the first. The second coat need not be sanded, its purpose being to combine with the first to form an insoluble mass hard as stone, and to give to the roof a neat, finished appearance.

Quickly-drying Oil Paint.

Boil for 15 minutes in an earthenware pot 1 part of soft curd soap in 3 parts of water. Pour the mass through a colander, wash it with cold water, and press out the water in a linen cloth. To 1 part of the curd soap add ½ part of unslaked lime and ⅔ part of water. Triturate the fat slime thus formed in oil or water with the necessary pigments. Walls, ceilings, stairs—in short, anything of stone, plaster of Paris, or zinc—can be painted with this. If the paint is to be used on wood, add $\frac{1}{10}$ part of linseed oil. Ochre, chrome yellow, Berlin blue, indigo, lead, and zinc, are best adapted for colouring substances. The mixture dries so quickly that 3 coats can be applied in a day. It is entirely without odour, and is about one-third the cost of ordinary oil paint.

Heat-Proof Paint.

Paint with good heat-proof properties, for smoke boxes, etc., can be made from 3 lbs. lamp black, 2 lbs. black lead, 1 lb. of black manganese oxide; these are mixed together; add ½ gal. of gold size, 1 pint of turpentine, and ½ pint of terebene; this, when thoroughly mixed in, will bring the mixture to the consistency of paint, and if about two coats of this are applied to surfaces exposed to heat, they will be found to resist same very well.

Fire-resisting Paint.

(1.)

20 lbs. finely pulverised glass, 20 lbs. finely pulverised porcelain, 20 lbs. any sort of stone in powder, 10 lbs. calcined lime, and 30 lbs. water glass (silicate of soda). The solid elements, having been powdered as finely as possible and sifted, are moistened and then intimately mixed with the water glass. This yields a syrupy mass that may be employed for painting, either alone or mixed with colour. The coating is applied with a brush, as other paints are, as uniformly as possible over the surface to be protected. The first coat hardens immediately, and a second one may be applied 6 hours or more afterwards; two coats are sufficient. The paint must be used immediately after it is made up.

(2.)

The most practical means so far discovered by the United States Forest Products Laboratory, Madison, Wis., for economically rendering small quantities of wood fire-resistant consists in the

use of fire-retardant paints. Ordinary whitewash or calcimine has proved in tests to be as fire-resistant as any paint covering tried, and it also possesses the advantages of cheapness and ease of application. While it will not prevent the burning of wood continuously exposed to a high temperature, a good coat of calcimine will decrease the likelihood of a blaze spreading from small sources of fire, such as flying sparks and matches. Calcimine is naturally more effective for interior than for exterior use. For work of the latter class the Forest Products Laboratory has developed an effective paint composed of linseed oil, zinc borate, and chrome green, which has maintained its fire-resisting properties through more than three years of exposure to the weather.

Heat-indicating Paint.

A paint for indicating an excessive rise of temperature in machinery bearings is composed essentially of a mixture of the double iodide of silver and mercury and copper mercuric iodide. The former is a pale yellow powder at normal temperatures, but turns to a vivid carmine at 90° to 100° C., while the copper salt, which is normally of a strong scarlet vermilion, changes to a chocolate brown at 60° to 70° C. A mixture of the two in the proportion of 85 per cent. of the copper salt and 15 per cent. of the silver changes promptly from vermilion to nearly black at 60° to 70° C. The paint is made with the aid of white shellac spirit varnish (100 grms. of the mixture to 70 cub. cm. of the spirit), and is applied in the form of a band or bull's-eye to the bearing. After the paint has become dry it is to receive a coat of colourless oil-proof varnish.

See also p. 1040.

Painting Portland Cement.

Portland cement work which is to be painted must be thoroughly hardened and dry. It is advisable to let the work stand for a year before oil paints are applied. The durability of the paint will be assured by, first, brushing over the surface with dilute sulphuric acid—one part of acid to 100 parts water—and allowed to dry before painting. A preparatory coating for oil paint is a solution of common water glass in three or four parts of water. Two applications of this, followed by a washing with water, and then another application of water glass, will be found effective.

Coal-Tar Paint.

(1) Coal-tar, 8 parts; Portland cement, 1 part; kerosene oil, 1 part. (2) Coal-tar 16, Portland cement 4, and kerosene 3 parts. The Portland cement neutralises the action of the tar on iron and steel, while the kerosene acts as dryer. It is suitable for painting ironwork of all kinds, and is a satisfactory coating, it is said, for ships' sides, and may also be used on galvanised iron.

Graphite Paint.

The best and longest records of satisfactory protection against corrosion are said to be held by graphite paints containing silica in intimate admixture with tough crystalline foliated graphite.

An example of this is the 'Foliac' Silica-Graphite Paint manufactured by *Graphite Products, Ltd., Battersea*, which is British manufactured throughout, and has been specified for a large number of steel structures, including Admiralty airship sheds, oil fuel tanks, gas holders, docks, bridges, station roofs, railway wagons, &c.

The relative covering power of foliated silica graphite paint is very high, and owing to the lubricating properties of the pigment the speed of application to the surface is very much more rapid than with other linseed oil paints. Owing to the large adhesion surface between the vehicle and the foliated graphite a very flexible tough paint is obtained which stands wearing action due to dust, for example, much better than paints which become brittle on drying. The resistance of the pigment to the action of the atmosphere found in industrial districts is due, of course, to the fact that it is chemically inert.

Bituminous Paints.

Bituminous paint is a good preventive to rust as it adheres closely to the material to be protected, it is strongly resistant to sulphurous vapours prevalent in the air of industrial centres, and very few of the mineral acids attack it, with the exception of nitric acid. Nitrous fumes have little or no action on the better bituminous paints. A good bituminous paint should dry within four or five hours, and the chances of injury by rain or similar eventualities during the setting are, therefore, correspondingly small. A high-class bituminous paint may be applied at a cost of something like a farthing per square foot with two coats of the paint applied. The life of a well-compounded bituminous paint extends up to twenty years' efficient protection.

Luminous Paint.

Mix 50 parts of lime with 20 parts of flowers of sulphur, heat them together in a closed crucible until all fumes cease to be evolved. When quite cold grind the product up with varnish or paint which is quite free from lead. Luminous paint produced from oyster shells is the most efficient in retaining its luminosity after dark. Take clean shells and, after washing them in warm water, place them in the fire for half an hour, and when cool, after removal, pound them up very small and fine, taking away any grey portions as being of no use, then put this powder in a crucible with alternate layers of flowers of sulphur, place on the lid and cement it round with sand made into a stiff paste with beer; as soon as this is dry, place the crucible in the fire and bake for one hour. Wait until quite cold before opening the lid. The product should be white; any grey portions must be separated as non-luminous. Sift it through fine muslin, and mix with either varnish or gum water. For use with buoys or in places exposed to the weather, varnish of the best quality only must be used.

VARNISHES.

Incombustible Varnish for Wood.

An application of a solution of equal parts of alum and isinglass to the place exposed to the flame prevents ignition, but not the transmission of heat. By coating wooden vessels with this varnish fluids may be boiled in them over an ordinary fire.

Varnish for Wood not acted upon by Boiling Water.

Boil in an untinned copper boiler 750 parts of linseed oil. Suspend in this, in a bag which must not touch the bottom, 150 parts of litharge and 90 parts of pulverised minium. Let the oil boil until it has assumed a dark brown colour; then remove the bag, and replace it by one containing 7 to 8 bulbs of garlic. Now melt 500 parts of pulverised amber in 60 parts of linseed oil over a strong fire; add it while boiling to the prepared linseed oil, and let it boil for 2 to 3 minutes longer, stirring it vigorously. Then take it from the fire, allow it to settle, pour off the clear liquid, and when cold put it in bottles, which should be hermetically closed.

Quick-drying Varnish.

A quick-drying varnish that is less liable to crack than that made from kauri gum is made in the United States from the nuts of the Chinese wood oil tree (*Aleurites fordii*). The tung (or wood) oil has also been found of special value for waterproofing cement.

Varnish to prevent India-rubber Gas-tubing from Leaking.

Treacle, 1¼ part; gum arabic, 2 parts; white wine, 7 parts; strong alcohol, 3¼ parts.

Waterproofing Material.

A new French material for waterproofing leather, cloth, paper, and other materials, consists of a mixture of eight parts of amylacetate and four of castor oil, with one part of sulphur chloride stirred into it. This forms a jelly, giving off hydrochloric acid; it liquefies after being kept tightly covered a few days, and, the acid being then neutralised with barium carbonate, gives a colourless solution on filtering. To make a varnish, nitrocellulose is dissolved in the liquid after the addition of alcohol or benzine.

Cellulose Lacquers and Varnishes.

Cellulose lacquers and varnishes are extensively used for motor-cars and other purposes where a brilliant finish coupled with great resistance to weather is desired. They are made by dissolving nitrocellulose or cellulose acetate in amyl nitrate or acetate, castor-oil, or other suitable solvent, and may be applied with a spray or a brush, according to the nature of the lacquer and the surface to be decorated.

Cellulose lacquers have been used for twenty-five years or more, but their great popularity is of recent growth. In many instances they have replaced oil enamels, but in numerous other cases the reverse has occurred. For motor-cars, the American cellulose lacquer finish is superior to the American oil-varnish finish, but inferior to the English oil-varnish. English cellulose lacquer finish is superior to the American product and approaches, but is not quite equal to, English oil-varnish. In appearance the cellulose lacquer finish and the oil-varnish finish are almost equal, and it is a question of workmanship rather than material which gives the advantage, sometimes to one and sometimes to the other. The relative durability remains to be proved, short time tests being unreliable. Cellulose lacquer is more liable to crack under vibration, but is more resistant to changes in temperature, and whilst it is harder than oil-varnish it is more brittle and more liable to peel.

The cost of cellulose lacquer is greater than that of oil-varnish, but in large quantities it is cheaper to apply, so that the cost of covering a given area is less with cellulose than with oil-varnish. Although the use of cellulose lacquers is increasing rapidly, these materials have not superseded oil-paints, water-paints, and stove-enamels. They are limited in scope, cannot be repaired so readily when damaged, and many of them are inflammable and produce vapours injurious to the health of those applying them. These are temporary disadvantages which will probably disappear as still further improvements are made in cellulose lacquers. In selecting such lacquers care should be taken to avoid those of poor quality, of which there are too many available.

METAL LACQUERS AND BRONZES.

Lacquer for Iron and Steel.

Mastic, 10 parts; camphor, 5 parts; sandarach, 15 parts; elemi, 5 parts. Dissolve in alcohol and apply without heat.

A Rustless Coating for Steel.

A solution of white wax in benzine applied with a camel-hair brush. When the film of wax hardens, the bulk of it is wiped off with a chamois leather, just sufficient remaining to prevent rust, but not to be noticeable.

Angus Smith's Coating for Pipes.

Coal Tar 1 cwt., Tallow 7 lbs., Quick Lime (slaked) 10 lbs., Pine Resin 4 lbs., Coal Naphtha sufficient to thin the composition to a degree suitable for proper coating. Heat mixture, and immerse pipes, and allow to remain until the same temperature is diffused through the mass; then withdraw pipes. This treatment leaves a very firm and hard coating of pitch. It is very essential that the mixture be heated to a proper degree, viz., 350° to 450° F. If heated too much the pitch will not adhere properly, but will scale off.

Bronzing Liquids.

(1.)

Sulphate of copper, 1 oz.; sweet spirits of nitre, 1 oz.; water, 1 pint.

(2.)

Solution of chloride of platinum, laid on surface with a feather. When dry, blacklead over with an ordinary blacklead brush, and then lacquer.

(3.)

Boil 1 oz. of ammonium carbonate and a like quantity of blue vitriol in 1½ pint of vinegar until the latter is nearly evaporated. Then add 1½ pint of vinegar in which has been dissolved ½ drachm of oxalic acid and a like quantity of sal ammoniac. Place the mixture (known as Walker's Chemical Bronze) over the fire until it commences to boil, then allow it to cool; filter and put by in well-closed bottles.

If a medal, etc., is to be bronzed, it is first thoroughly cleansed, then heated, and the liquid applied by means of a badger-hair brush. In a short time boiling water is poured over the medal, and when dry it is rubbed with a cotton rag dipped in oil, and then with dry cotton.

Browning for Gun Barrels.

Tincture of muriate of iron, 1 oz.; nitric ether, 1 oz.; sulphate of copper, 4 scruples; rain water, 1 pint. When the barrel is finished let it remain in lime-water for a short time; then scratchbrush and apply bronzing.

Lacquer for Gun Barrels after Browning.

Shellac, 1 oz.; dragon's blood, ½ oz.; rectified spirit, 1 quart. Dissolve and filter.

To Chemically Blacken Brass.

Dissolve copper in nitric acid (out of doors) until all action ceases; when cold decant into another jar.

Sand-blast work, or clean in hot lye and soda; dry in sawdust; heat to 212° F.; immerse in the (cold) nitrate solution; remove and heat again sufficiently to dry off solution and burn off green colour; repeat if necessary; cool and free from oxide by brushing; dip in ammonia; rub dry with soft cloth or in sawdust—work is then brown. To make it dead black, heat just enough not to burn hands, and rub with soft leather and fine olive oil; heat, to dry oil.

Highly-polished work, if well cleaned and dipped in commercial ammonia before applying nitrate, will take a permanent black.

Sand-blasted work takes a black that cannot be removed by ordinary wear.

Black-bronzing Aluminium.

(1) Immerse the articles, after being thoroughly cleaned, in a hot solution containing 8 oz. of white arsenic, 8 oz. of iron sulphate, ¼ gallon of hydrochloric acid, and ¼ gallon of water. When sufficiently blackened the articles are removed, washed and lacquered. A more adhesive deposit may be obtained by adding to the solution a small quantity of ammonium molybdate and yellow prussiate of potash. (2) Paint the articles with a solution made by dissolving 60 grammes of copper chloride in 300 c.c. of water and add ammonia in excess to re-dissolve the precipitate first formed. Then heat the articles, care being taken not to melt the aluminium. A deeper black may be got by repeating the process, or by dipping the articles in a solution of sodium sulphide.

Black Finish on Steel Shears, etc.

Prepare a saturated solution of caustic soda and add about ¼ lb. of saltpetre to a five-gallon solution. Boil the solution for a short time, and allow it to cool. The clear liquid should only be used, and this should be brought to the boiling point in an iron kettle. The articles should be wired as for plating and immersed in the solution. The articles will take on a grey colour at once with black underneath, and should be left in the solution until the grey finish disappears and a beautiful black remains. Rinse the articles in cold water, dry in sawdust, oil with linseed oil and wipe clean. The resulting finish will be a fine blue-black that wears well.

LUBRICANTS AND OILS.*

Greases for Railway Axles.

(1.)

Water, 1 gallon; palm oil, 6 lbs.; clean tallow, 3 lbs.: common soda, ½ lb.

(2.)

Tallow, 8 lbs.; palm oil, 10 lbs. Heat to 212° F., and well stir.

Antifriction Grease.

(1.)

Tallow, 100 lbs.; palm oil, 70 lbs. Boil together, and when cooled to 80° F. strain through a sieve and mix with 28 lbs. common soda and 1½ gallon of water.

(2.)

Blacklead, 1 part; lard, 4 parts.

Rosin-Oil Soap.

90 lbs. powdered slaked lime, stirred into 100 lbs. rosin oil. Heat the mixture, constantly stirring it well until a uniform paste of the consistence of syrup is obtained. This rosin oil is a component of all the patent wagon greases.

Blue Patent Grease.

2 lbs. powdered slaked lime, heated in 550 lbs. of crude rosin oil for 1 hour, and then allowed to cool. Skim the oil, and stir in 10 to 12 lbs. of rosin-oil soap, until the compound is of a butter consistency and of a blue colour.

Yellow Patent Grease.

1 part turpentine, 20 parts caustic lye. Add to 350 parts of blue grease.

Black Patent Grease.

2 parts lampblack, 110 parts blue grease.

Patent Palm-Oil Wagon Grease.

Melt 10 lbs. rosin-oil soap in 10 lbs. palm oil: add 550 lbs. rosin oil, with as much rosin-oil soap as will give the whole the consistence of butter; finally, add 7¾ to 10 lbs. of caustic soda lye.

Adhesive Grease for Machine Belts.

Lubricate the belts with fish oil to which 10 per cent. of tallow has been added. This will make them flexible, and augment their friction on the pulleys.

Grease for Waterproofing Leather.

Oleic acid, 24 parts; crude stearic acid, 6 parts; ammoniacal soap, 18 parts; extract of tannin, 6 parts; water, 24 parts. Melt the oleic acid together with the stearic acid; then add gradually the ammoniacal soap, the extract of tannin, and finally the water. The ammoniacal soap is obtained by adding to heated oleic acid caustic ammonia until, after continued stirring, the odour of ammonia remains apparent and the whole congeals to a jelly-like mass.

Cooling Compound for Hot Bearings.

(1.)

Mercurial ointment mixed with black cylinder oil and applied every quarter of an hour, or as often as expedient. The following is also recommended as a good cooling compound for heavy bearings:—Tallow, 2 lbs.; plumbago, 6 ozs.; sugar of lead, 4 ozs. Melt the tallow with gentle heat, and add the other ingredients, stirring until cold. For lubricating gearing, wooden cogs, etc., nothing better need be used than a thin mixture of soft soap and black lead.

(2.)

For cooling a hot bearing Professor Lecocq, of the Charleroi Higher Industrial School, recommends that the oil usually employed for lubrication be dissolved in an equal quantity of petroleum spirit, the evaporation of which latter will, he says, afford the cooling desired.

---

Watchmaker's Oil.

Expose the best olive oil to a temperature a few degrees below the freezing point, which will cause all foreign substances to separate. Pour off carefully the supernatant clear oil, and filter through a cup of linden wood or pith of elder wood. By this process an oil is obtained which will remain liquid for several years, and does not attack the delicate machinery.

Neat's-foot oil treated in the above manner furnishes a less useful oil, since it loses much fatty matter by exposure to cold.

A very useful oil is obtained by dissolving 1 part of pure neat's-foot oil in 3 of pure benzine. Allow the compound to remain for several days in a closed vessel; then filter, and expose the solution to a temperature of 40° F., at which it is again filtered, and the benzine distilled off. The oil should be kept in small, dark vials protected from the air.

A very fine lubricant for clocks and watches is, according to Artemus, obtained by mixing 2 parts of solar oil with 1 of rape-seed oil.

To test the fitness of Oils for Lubricating Watches and Clocks.

Pour a drop of the oil to be tested upon different metal plates, as iron, brass, tin, lead, etc.; keep them in a place free from dust, and examine the drops during 8 to 14 days in regard to their liquidity. Oil remaining liquid after the lapse of this time can be safely used.

Viscosity of Various Standard Oils.

Description.	Viscosity.	
	At 70° F.	At 120° F.
Sperm oil	100	45
Whale oil	190	70
Olive oil	213	75
Lard oil	225	78
Neatsfoot oil	247	80
Rape-seed oil	250	88
Axle oil	600	120
Valve oil	—	550
Cylinder oil	—	700

In the above table sperm oil is taken as the standard for viscosity at 70° F.

The viscosity of thick oils can be greatly reduced by adding 8 per cent. of naphthalene to the oil.

An objectionable characteristic in an oil is its tendency to become resinous with use, due to the oil undergoing the process of oxidation. This change in the oil indicates, to some extent, the degree of refining process the oil has undergone. A simple test can be made in the following way :—Place a small quantity of oil in a glass beaker and put in a nearly equal amount of nitric acid. Should the oil have no tendency to gum, the acid and oil will combine and get very thick, while should there be any objectionable characteristic the oil will remain thin.

CLEANING AND PRESERVATIVE COMPOSITIONS.

To clean Brass.

Oxalic acid, 1 oz. Rotten stone, 6 oz.; powdered gum arabic, ½ oz.; sweet oil, 1 oz. Rub on with piece of rag.

Soap for cleaning Metal-work.

The soaps used for cleaning metal-work usually consist of mixtures of vaseline, oleic acid, and fat, mixed with a small quantity of rouge. When freshly prepared they leave nothing to be desired; but, unfortunately, such mixtures soon turn rancid and become unfit for use. A newer soap for metal-work, which is stated to be free from this objection, is made from cocoanut butter in the following way :—2·5 kilogrammes of the butter are melted in an iron vessel, together with a little water, and to the mixture is added, with constant stirring, 180 grammes of chalk, 87·5 grammes of alum, 87·5 grammes of cream of tartar, and 87·5 grammes of white lead. This mixture is then poured into moulds and allowed to solidify. The soap so obtained is made into a paste with water, rubbed over the metal to be cleaned, and finally removed by a dry rag or chamois leather.

To clean Grease from Paper.

(1.)

Warm the spotted part, and press blotting-paper upon it until all the grease is extracted that is practicable by this method; then with a brush apply very hot turpentine, and wash off with alcohol.

(2.)

Apply benzine collas freely to the spot.

To clean Marble.

Powdered chalk, 1 part; powdered pumice stone, 1 part; soda, 2 parts. Mix with water. Paint over marble; then clean, and wash off with soap and water.

To clean Grease from Stone or Marble.

Soft soap, 1 part; fuller's earth, 2 parts; potash, 1 part. Mix with boiling water. Lay it on the spots, and let it remain for a few hours.

A Solvent for Rust.

It is often very difficult, and sometimes impossible, to remove rust from articles made of iron. Those which are very thickly coated are most easily cleaned by being immersed in a solution (nearly saturated) of chloride of tin. The length of time they remain in this bath is determined by the thickness of the coating of rust. Generally twelve to twenty-four hours is long enough.

To cleanse Paint Brushes from Dried-in Paint.

Suspend the brush in a tumbler containing a solution of 1 part of crystallised sodium carbonate in 3 of water, in such a manner that it hangs several inches from the bottom of the tumbler. Let it stand from 12 to 24 hours in a moderately warm place (140° to 150° F.). The dried paint will be softened so much that it can be easily washed out with soap and water. Brushes which have become as hard as stone can be restored by this process.

To Remove Rust from Iron.

(1.)

Freely apply turpentine or paraffin oil, leave for twelve hours, and then rub with the finest emery cloth.

(2.)

Dip in strong hot potash bath, for about ½ hour. Then immerse in a cold muriatic acid pickling solution—2 parts water, 1 acid. This removes rust in a few minutes, the metal being attacked but very little. Without the potash it will take about 65 minutes against 4 when both baths are used. The appearance of the rust when treated is black and soft and it can almost be entirely rubbed off with the hands. The metal so treated has a smooth, glossy finish.

(3.)

A dip of 40 parts of muriatic acid and 60 parts of water is effective for removing rust. After the rust has been removed, it is necessary to dip the steel in a strong alkaline bath to remove every trace of acid. The alkaline solution usually employed for this purpose is composed of 2 oz. each of soda ash, sodium cyanide, and caustic lime.

To Remove Rust from Iron Electrically.

A very simple and effective way of cleaning rusted iron articles, no matter how badly they are rusted, consists in attaching a piece of ordinary zinc to the articles, and then letting them lie in water to which a little sulphuric acid is added. They should be left immersed for several days, or a week, until the rust has entirely disappeared, the time depending on how deeply they were rusted. If there is much rust, a little sulphuric acid should be added occasionally. The essential part of the process is that the zinc must be in good electrical contact with the iron; a good way is to twist an iron wire tightly around the object, and connect this with the zinc, for which a remnant of a battery zinc is suitable, as it has a binding post. Besides the simplicity of this process, it has the great advantage that the iron itself is not attacked in the least as long as the zinc is in good electrical contact with it. When there is only a little rust, a galvanised iron wire wrapped around the object will take the place of the zinc, provided the acid is not too strong. The articles will come out a dark grey or black colour, and should then be washed thoroughly and oiled. The method is specially applicable to objects with sharp corners or edges, or to files and other articles on which buffing wheels ought not to be used. The rusted iron and the zinc make a short-circuited battery, the action of which reduces the rust back to iron, this action continuing as long as any rust is left.

To keep Machinery from Rusting.

Take 1 oz. of camphor, dissolve it in 1 lb. of melted lard; mix with it (after removing the scum) as much fine blacklead as will give it an iron colour. Clean the machinery, and smear it with this mixture. After 24 hours rub clean with soft linen cloth. It is stated that this mixture will keep machinery clean for months under ordinary circumstances.

To protect Iron and Steel from Rust.

The following method is but little known, although it deserves preference over many others: Add 1¾ pints of cold water to 7 ozs. of quicklime. Let the mixture stand until the supernatant fluid is entirely clear. Then pour this off, and mix it with enough olive oil to form a thick cream, or rather to the consistency of melted and recongealed butter. Grease the articles of iron or steel with this compound, and then wrap them up in paper; or, if this cannot be done, apply the mixture somewhat more thickly.

To keep Tools from Rusting.

Half-ounce camphor dissolved in 1 lb. melted lard: skim and mix in as much black-lead as will give it an iron colour. Smear tools, and after 24 hours rub clean with soft linen cloth.

Or, 6 oz. lard to 1 oz. rosin. When semi-fluid it is ready for use.

Or, use vaseline, to which, when warm, a little powdered camphor has been added.

To remove Rust from Tools.

Tools which have become very rusty should be treated with a chemical solution, instead of trying to scour the rust off by means of emery cloth. A good solution for removing rust may be made as follows. Into one quart of distilled water dissolve, little by little, sufficient chloride of tin to obtain a saturated solution, that is, until the water will not dissolve any more of the salt. Put the tool into a receptacle containing the solution and let it stand over night. In the morning rinse the solution off in running water and dry thoroughly with a piece of chamois or cloth.

Blueing Steel.

Outfit.

The outfit consists of a cast-iron kettle, one tank for boiling water, and one tank for oil (aquiline). The mixture consists of nine parts of saltpetre, by weight, and one part pyrolusite. The articles are hung in perforated baskets. A scraper is necessary for the melting kettle to stir the solution and to scrape the sediment from the bottom.

Method.

The desired temperature for treatment is obtained when all the mixture has melted and begun to boil, and when a pinch of fine sawdust thrown in bursts into flame the moment it reaches the surface. The temperature must be kept constant to give good results. In operation, the full basket may be hung on the chain at one end of a lever and lowered into the solution. The articles are left in for three minutes, then are slowly lifted out to allow the surplus solution to drain off; they are then dipped into hot water to clean off the solution; after the water has drained off, the articles are dipped into the oil and taken out as quickly as possible and allowed to drain. It is essential to note that there be no rust on the work, and that red-hot cast iron is attacked by these chemicals.

Blueing Small Screws.

Use a boiling bath composed of:

Water	1 gallon.
Hyposulphite of soda	2 ozs.
Acetate of lead	2 „

The hyposulphite of soda and the acetate of lead are first dissolved in the water and the whole is then brought up to boiling point. The work, which must be absolutely clean and free of grease, and preferably polished, is immersed in the bath for a few seconds, and then withdrawn. At first the work will be a kind of yellow, changing to red and then to blue almost immediately. The work is rinsed in water and quickly dried. Changing the length of time during which the work is immersed in the bath will give varying depths of colour. When the desired tint is obtained, note the time immersed, and give subsequent dippings the same period in the bath.

The brilliancy of the blues obtained by the above method is greatly enhanced if the work is copper plated before immersion in the colouring bath. The plating may be accomplished by the dipping process. To a quantity of distilled water add all the copper sulphate it will dissolve, then for every four ounces of distilled water add from 10 to 14 drops of sulphuric acid. Start with 10 drops in the first instance and add more sulphuric acid if required. Before coppering it is absolutely essential that the work be free from grease. It should be noted that in all colouring processes the higher the initial polish on the work the greater the brilliance of the finished work.

(*'Machinery.'*)

Blueing Small Hardened Steel Springs Without Heating.

Thoroughly clean the springs in boiling lime water and afterwards remove any remaining lime by means of a brush. Dip the springs in a nitric acid bath; wipe clean and oil; linseed oil is generally used for this purpose. (*W. R., 'Machinery.'*)

Waterproof and Fireresisting Boards.

The boards are first laid in a waterglass solution of 5° to 10° Bé., where they are left 10 to 12 hours, when they are taken out and allowed to drip off. After drying, they are placed in a solution (gravity 2° to 3° Bé.) of calcium chloride, magnesium chloride, and ammonium chloride. In this they are left four to six hours, and after dripping off and drying again, they are ready for use.

MISCELLANEOUS.

To Prevent Rusting-in of Screws.

In machines exposed to heat or moist air the screws soon rust in, even with the use of oil, which later on renders it difficult to take the machines apart. By dipping the screws before use in a thin paste of graphite and oil they can be readily taken out, even after years.

Drilling Glass.

To drill holes in glass a common steel drill, well made and well tempered, is the best tool. Whilst drilling, the hole should be moistened with turpentine in which some camphor has been dissolved.

To drill a large hole in thin glass, make in a piece of wood a hole of the size required, and fasten the wood with beeswax upon the glass so as to act as a guide. A piece of brass or copper tubing, of the size of the hole required, is placed in the hole in the wood, supplied with emery powder and water, and is twirled round between the fingers or by means of a bow-string. This will cut a hole in a few minutes.

To Divide Glass Bottles.

Breaking glass tubes or vessels with a clean edge by the aid of a string dipped in an inflammable oil is a well-known method, but the latter is not suitable for large vessels, such as a carboy; to break such vessels, fill to point required with cold water, then pour boiling oil over surface of water: before oil has time to cool, dash cold water on outside of vessel, when a clean break is said to result.

A still better method is to make a small mark, with a triangular file, at the point where the break or division is required. A tiny gas flame, not larger than $\frac{1}{8}$ in. diameter, is then applied to the file-mark. If a crack does not start quickly the hot glass is wetted with a drop of water. When a crack has started the flame is held in contact with the glass, just in front of the crack; the crack will then extend to the flame and by causing the flame to travel, step by step around the vessel, complete severence will be effected with accuracy and certainty.

To Cut Glass Tubing of Large Diameter.

Nick the glass tube with a file or a cutter at the point where the fracture is desired. Wrap three or four thicknesses of blotting paper around the tube about $\frac{1}{4}$ in. from each side of the mark, the blotting paper being held in place by copper wires. Soak the blotters with water, and expose the narrow section of tube between the two wet blotters to the heat of a bunsen burner. The flame will cause a fracture starting at the file nick and extending in almost a straight line around the tube. The method describes for glass bottles (above) may also be used.

Cutting Glass under Water.

Cutting a glass sheet with a pair of scissors may seem difficult, but it is not, although the job must be done under water and both the glass and scissors must be submerged. A good way is to first cut a paper the size or shape of the glass desired; place it on the under side of the glass for a pattern. It is not expected that it is possible to cut through the centre of a large piece of glass, but by trimming a little at a time a good job can be done. The cutting sensation is a good deal the same as that of cutting cardboard.

To make Ivory and Bone Permanently White.

Hydrated oxide of zinc is dissolved in ammonia and the articles laid in it. To remove the yellow tint, a few drops of an aqueous solution of blue vitriol is added; after impregnation the articles are repeatedly washed with cold water, dried in the air and polished. The zinc-oxide of ammonia solution is prepared as follows:—40 parts by weight water mixed with 25 parts of pure zinc, with (after a quarter of an hour) 50 parts concentrated hydrochloric acid added. To the zinc solution 150 parts hot water is added, then (gradually stirring the while) caustic ammonia until the precipitated white hydrated oxide of zinc is dissolved.

Hard Rubber.

The finest grade of hard rubber, such as is found in a good comb or fountain pen, may contain 75 per cent. rubber and 25 per cent. sulphur, and may have been vulcanised ten hours. The specific gravity of pure hard rubber ranges from 1·12 to 1·25. The tensile strength in the finest and purest grades may be over three tons, and the dielectric strength is specified by the United States Navy for sheets at 10,000 volts per $\frac{3}{32}$ in. of thickness.

Fibre.

There are three kinds of fibre in general use—viz., two kinds of vulcanised fibre, known as hard and flexible, and horn fibre.

The flexible is restricted to such uses as pump valves, washers and gaskets. The tensile strength of vulcanised fibre varies from 10,000 lbs. to 20,000 lbs. per sq. in. (as compared with 3,000 lbs. to 6,000 lbs. for leather). Its resistance to compression varies from 40,000 lbs. to 60,000 lbs. per sq. in. (for wood it varies from 3,000 lbs. to 11,000 lbs.). Its resistance to shearing varies from 9,000 lbs. to 13,000 lbs. per sq. in. (compared to wood, with the grain, 225 lbs. to 906 lbs.; to aluminium casting, 12,000 lbs.; and to aluminium forgings, 16,000 lbs.). There is no clearly defined elastic limit, but it approximates 4,000 lbs., and there is no permanent set even at rupture point. The specific gravity is about 1·3, varying from 1·2 to 1·5 (sp. gr. of pure aluminium in a cast state is 2·58; of cork, 0·24; of wood, 0·35 to 1·33). It possesses the strength and density of a metal, yet is elastic and nearly as light as hardwood. A square foot of $\frac{1}{8}$ in. fibre weighs about $\frac{7}{8}$ lb. and the same area of 1 in. stock about 7 lbs.—i.e., about 20 cub. ins. to the pound.

Vulcanised fibre is insoluble in all the ordinary solvents, and is not affected by immersion in alcohol, ammonia, benzine, or any of the animal, vegetable, or mineral oils. It absorbs water freely, and swells when wet, but is not otherwise injured. When heated this fibre does not melt or soften, but at a high temperature it chars and loses its elasticity. Vulcanised fibre is not brittle, and will stand a great amount of pounding and rough usage. It can be machined, and will take a fine polish, but cannot be moulded.

One of the purposes to which vulcanised fibre is being applied is the thrust bearings in light sensitive, drilling machines. Ball bearings cause endless trouble in this position if one of the balls fractures or chips, and it has been found that a fibre disc answers the purpose admirably. The permeability of the fibre to oil renders it self-lubricating, and its life under these conditions is remarkable.

To Face Oilstones.

On a sheet or plate of iron with an accurately even or straight face (it ought to be planed) scatter a little emery or fine sand, add a little water, and rub the face of the stone on the sheet, renewing the emery or sand and water as requisite, finishing with an addition of water without emery or sand.

Etching and Etching Fluids.

The nearest approach to a perfect protective for general purposes is beeswax of the proper consistency, which can be easily applied in any desired thickness. Before applying the wax it is important that the surface be thoroughly clean and absolutely dry, and the difference in temperature between the wax and the article to be etched should be slight. If it is necessary to dip the piece into melted wax, the article should be kept immersed for a few moments until it acquires the same temperature as the molten wax. The design is cut in the wax and through to the metal, after which the etching liquid is applied.

The following fluids have been found to work satisfactorily:

Iron and Steel.—Hydrochloric acid (full strength) should be used. Nitric acid, however, must not be used.

Brass.—Nitric acid.

Copper.—A mixture containing 2 parts of nitric acid and 1 part of sulphuric acid.

Silver.—Nitric acid, 3 parts; water, 1 part.

Gold.—A mixture containing 1 part of nitric acid and 3 parts of hydrochloric acid. The mixture should be prepared just before being applied, and should be used warm, under a hood or fume closet.

Platinum.—The same mixture as that used for gold.

Lead.—Nitric acid.

Aluminium.—A 10 per cent. solution of caustic soda or potash.

Zinc.—A mixture containing equal parts of hydrochloric acid and water, used warm.

Glass.—Hydrofluoric acid. The article may be immersed in the liquid acid for a few minutes or it may be exposed to the fumes for five to fifteen minutes. Extreme caution should be used in handling this acid, using rubber gloves for the hands and a lead or hard rubber container for the acid. Contact with the skin will cause severe burns, and the action seems to be continuous, producing burns far more severe than those caused by the mineral acids.

All the acids may be used full strength, but if the etching is to be of considerable depth most of them may be diluted with water before applying. This will require more time, but will produce a cleaner cut. The exception to this is the mixture of gold and platinum, which must always be used full strength and applied as warm as the melting point of the wax will permit.

Bending Small Metal Tubes.

Put a cork or plug into one end and fill with slightly damp sand well rammed in, then close with another cork; heat the tube until it is just uncomfortably hot to the hand, and then bend round a bit of board sawn to the required curve.

In making coils and spirals of small tubing, the Bureau of Standards at Washington has adopted the plan of filling the tubes with ice. This has the advantage of being very easily got rid of after the completion of the operation, and has proved very effective. To produce the ice filling, the tube, after charging with water, is immersed in a bath of ice and salt.

To Drill Hard Steel.

Use turpentine instead of oil; it will drill readily even when the drill lubricated with oil will not touch the metal.

Turning and Cutting Aluminium.

One of the best lubricants for cutting aluminium in the lathe is paraffin; this prevents tearing, and enables a better finish to be obtained.

To Remove a Stubborn Nut.

Heat the spanner end and place on nut for a moment or two or apply a red hot bar to the nut; this will expand the nut only, whereas using a blow-lamp, etc., heats both nut and bolt. If the above method fails, the nut should be split.

Silvering a Mirror.

(Up to 14 square inches area.)

Well scrub glass with brush, soap, and hot water; rinse repeatedly in cold water; soak in nitric acid for few minutes; rinse in distilled water. Do not touch surface after soap stage.

Solutions.

(*a*)		(*b*)		(*c*)	
Silver nitrate .	50 grs.	Grape sugar .	50 grs.	Caustic potash .	50 grs
Distilled water .	1 oz.	Distilled water .	1 oz.	Distilled water .	1 oz.

Add strong ammonia drop by drop to (*a*), when a yellowish precipitate will form, and later liquid will clear. No more ammonia must then be added; swirl after each drop. Add (*c*), when black precipitate will form; add ammonia drop by drop until solution clears; add 2½ ozs. distilled water and mix in sugar solution (*b*). *Immediately* put into dish and carefully insert glass with face (downwards) just below the surface. When sugar is added solution becomes cloudy, so it should only be added when quite ready for use. Leave glass undisturbed for 30 minutes. Remove glass and again wash in distilled water. Drain for few minutes and swish off any drops of water. If cloudy, polish with a pad of cotton wool covered with soft chamois leather and jewellers' rouge, by light circular strokes. Lacquer with No. 2 cold colourless lacquer from Messrs. Gedge, 90 St. John's Street, Clerkenwell. Back with Brunswick black. Absolute cleanliness in vessels and liquids is essential to success. It is usually cheaper and more satisfactory to send the glass to a mirror-maker.

Size of Clock Dials.

Allow 1 ft. diameter for every 10 ft. from the ground, and then add 6 ins. to this; thus, if the dial is to be 40 ft. from the ground, the diameter should be 4 ft. 6 ins.

Wire Drawing.

Wire may be reduced in diameter or *drawn* by forcing it through holes in a piece of steel or other substance. A steel die is used where practicable but for some purposes diamond dies are preferable. The diamonds used are either natural stones or chips from large stones used in jewellery. For a hole ·055 in. in diameter a 5-carat stone is needed, whilst stones weighing half-a-carat suffice for dies with holes from ·014 in. down to ·009 in. in diameter and under. In copper wire the smallest size made commercially is 0·002 in. in diameter. Thirteen diamonds are needed to reduce the wire from ·010 in. in diameter to 0·003 in. in diameter. Wires thinner than ·002 in. in diameter are exceedingly expensive to make. A lot drawn for exhibition purposes from ·0022 in. in diameter down to ·001 in. in diameter took 7 drafts. The life of the diamonds when drawing copper wire is six months to a year, provided the stones are of good size, hard, smooth, and well drilled. The weight produced per operator per day falls very rapidly as the size of the wire is reduced. Thus, whilst one man will produce 1,100 lbs. per day of No. 22 (B. and S. gauge), he can only draw 45 lbs. of No. 40 (B. and S.). Diamonds are also used for drawing steel, though they are not economical, nor do they produce a better quality of wire than steel die-plates; but if fine steel wire is wanted very round and true to size, the diamond dies seem necessary. A steel die will not keep to size for more than one coil of No. 33 wire or finer. The life of a diamond is much shorter on steel than on copper, averaging only about three days when it must be polished out for the next larger size. The surface produced on steel wire is not so smooth when diamonds are used as it is with steel. The speed at which the wire is drawn appears to have little effect on the life of the diamond die, which depends solely on the length passed through. About 200 lbs. weight of steel wire can be drawn through a No. 32 (B. and S.) diamond die-plate before it is off size, 15 lbs. through holes ·005 in. to ·003 in. in diameter, and less than 1 lb. through holes smaller than ·002 in. in diameter. The smallest commercial size is ·0025 in. steel brush wire, drawn from low or medium carbon steel. Difficulty was at one time experienced in drawing hard music wire smaller than ·012 in. in diameter without breaking the diamond; but nowadays it can be drawn as small as ·005 in. in diameter, using 2 to 2½-carat diamonds for the dies. Below about ·009 in. or ·008 in. diameter, however, music wire becomes very curly, and no method of keeping it straight has yet been discovered.

Cracks in Metal.

A crack in a piece of metal is prevented from extending further by the well-known means of drilling a hole where the rent ends; but when the hole is not bored on just that spot the crack is apt to continue beyond the hole. To facilitate the search for the exact point, moisten the cracked surface with petroleum, then wipe it, and immediately rub it with chalk. The oil that has penetrated into the crack exudes, and thus indicates with precision where the crack stops. The best method of healing cracks is by electric or acetylene welding.

Rendering Celluloid Incombustible.

In order to overcome the undesirable quality of celluloid to ignite, it may be dissolved in a mixture of ether and alcohol and added to an ether-alcohol solution of ferric perchloride. The clear syrupy liquid is poured into a suitable vessel and is left for spontaneous evaporation. The resulting substance of shell-colour is, after washing and drying, a celluloid of great pliability and transparency, and is incombustible.

See also "Celluloid," by Dr. Beckmann: Fr. London, Scott, Greenwood & Son, 8 Broadway Ludgate Hill, London, E.C. 4. Price 8*s.* 6*d.*

Wood-Worms in Oak.

It is stated that the most effective means of treating oak work when attacked with wood worm is to give it several coats of paraffin, well soaked into the wood. This should be done by a careful workman, making quite sure that every hole has been well soaked with the paraffin; the paraffin does not damage the oak, but has a tendency to improve the colour.

The extermination of the *Xestobium tessellatum* in the oak roofing of Westminster Hall has been effected by spraying the timber with a mixture of 50 per cent. tetrachlorethane, 6 per cent. cedarwood oil, 2 per cent. solvent soap, 2 per cent. paraffin wax, and 40 per cent. trichlorethylene. The tetrachlorethane is a perfect insecticide, but it is so dangerous that those who handle it must use gas masks.

Thermostatic Metal.

Thermostatic metal, manufactured by the *British Thomson-Houston Company, Ltd.*, has appearance a homogeneous metal, is formed of two metal strips having widely different coefficients of expansion. The two metals are welded together along their entire length, and are quite inseparable under normal working conditions. When the duplex strip is subjected to change of temperature, one half will expand more quickly than the other, causing the strip to bend. A change of one degree of temperature is said to affect its curvature to a measurable extent and practically instantaneously. In bending, it exerts a force sufficient for the direct operation of levers, the opening and closing of ventilators, etc. The metal can be cut, stamped, or machined; it is supplied in various thicknesses from 0·015 in. to 0·25 in.

Setting a Spirit-Level Glass.

A simple method of setting a spirit level glass is to use a small piece of putty to support each end temporarily. The plastic putty can be made to hold the glass in the required position, it being an easy matter to depress either end so that it will be parallel or level with the working surface of the levelling bar. When properly levelled up in this way plaster of Paris is poured around the supporting ends of the glass and allowed to set. The glass will then be held permanently in place. (J. H. B., *Machinery*).

Supporting Power of Ice.

Ice 1½ inches thick will support a man.		Ice 10 inches thick will support a crowd.	
„ 4 „ „ „	cavalry and light guns.	„ 18 „ „ „	a railway train.
„ 5 „ „ „	an 84-pound cannon.		

Removing Enamel.

The ordinary paint-removers, designed to remove air-dried paint and varnishes, are not adapted, or intended to be used, for the removal of baked enamel from metallic surfaces such as those of automobiles. It is customary in the removal of baked enamel, particularly enamel which is baked under high temperatures, to laboriously chip it off. D. F. Clark, of Harrisburg, Pa., has compounded a body (U.S. Patent No. 1,495,547) which may be applied with a brush, and which will adhere to the enamelled surface, and on allowing it to remain for from 15 mins. to 2 hours, depending upon the temperature at which the enamel was baked, the enamel may be easily brushed off. The best results are obtained from a mixture of the following ingredients in the proportions mentioned; 20 parts of methyl acetone; 20 parts of denatured alcohol; 10 parts of aqua ammonia (of 26° to 32°); 10 parts ammonia carbonate; 15 parts benzol; 10 parts xylol; 5 parts paraffin wax; 5 parts celluloid chips; 5 parts soap. The benzol, xylol, and methyl acetone are boiled, and the wax and celluloid are stirred in until thoroughly incorporated. The mixture thus far made is then permitted to cool. After cooling, the denatured alcohol is added. Finally, the ammonia is added. The purpose of the celluloid and the wax is to impart a viscous consistency to the mass and prevent evaporation of the volatile constituents. Some enamelled metals have so adhesive an enamel that this treatment will not remove it.

Flow of Sand.

The velocity of flow of sand and other fine materials through openings of various shapes and in different circumstances, is determined mainly by the size of the particles and of the opening, but is slightly diminished by angularity of the particles or by moisture on them. The specific gravity of the particles, the height of the material above the opening, and the shape of the upper contour of the material have little effect. If D is the diameter of the opening, d that of the particles, both in inches, the mean velocity of flow V in feet per second is given with sufficient accuracy for most practical purposes by the equation, $V = (D - 2d)/\sqrt{D}$.

SECTION XLIII

LENGTHS — SURFACES — WEIGHTS — CAPACITIES — WIRE GAUGES — FOREIGN WEIGHTS, MEASURES, AND MONEY, WITH THEIR ENGLISH EQUIVALENTS—SIZES OF PAPER

(pages 2807-2825)

(Revised by S. W. Attwell, of the National Physical Laboratory)

SECTION XLIII

LENGTHS—SURFACES—WEIGHTS—CAPACITIES—FOREIGN MEASURES—WIRE-GAUGES—SIZES OF PAPER, etc.

(Revised by S. W. Attwell, of the National Physical Laboratory.)

The accepted relations of English Imperial to International Metric Measures are thus given by the Standards Office of the Board of Trade :

1 inch = 25·399978 mm.; 1 metre = 39·370113 inches; 1 gallon = 4·5459631 litres; 1 litre = 1·75980 pint; 1 pound = 0·45359243 kilogram; 1 kilogram = 2·2046223 pounds.

In 1893 the United States of America recognised the metre as the fundamental standard of length, and adopted the conversion value of 1 metre = 39·37 inches.

10 penny diameters = 1 ft.; halfpenny = 1 inch; 5-shilling piece = 1½ inch. Weight of 3 pennies, 1 five-shilling piece, or 5 shillings, each = 1 oz.

LENGTHS.

English.

The length of the standard yard of 36 inches is such that a pendulum vibrating seconds of mean time, temperature 62° F., at the level of the sea and latitude of Greenwich, has a length of 39·1393 inches.

Miles.	Furlongs.	Chains.	Rods.	Yards.	Feet.	Inches.

GUNTER'S SURVEYING CHAIN.

7·92 inches = 1 link. 100 links = 1 chain 4 rods, or 22 yards. 80 chains = 1 mile.

ROPES AND CABLES.

1 cable-length = 120 fathoms = 720 feet. 1 fathom = 6 feet.

GEOGRAPHICAL AND NAUTICAL MEASURES.

1 degree of a great circle of the earth round the equator = 69·174 statute miles = 365,239 feet. 1 nautical mile (knot) = 6,080 feet. 1 telegraph mile = 6,087 feet.

LOG-LINE.

The log-line should be about 150 fathoms long, and 10 fathoms from the log to the first knot on the line. If half-a-minute glass is used, it will be 50·66 feet between each succeeding knot. For 28-seconds glass it will be 47·29 feet = 7·88 fathoms per knot. This is the length of knot by calculation, but practically it is shortened to 7·5 fathoms per knot for 28-seconds glass.

The Metric Carat.

By decision of the Standards Department of the Board of Trade, the metric carat of 200 milligrams, and its necessary multiples and sub-multiples, are standard weights in the United Kingdom.

CAPACITIES.

English.

Gallon.—The standard gallon (*International Bureau of Standards, Paris*, 1921) measures 277·420 cubic inches, and contains 10 lbs. (avoir.) weight of distilled water (weighed in air against brass weights) at the temperature of 62° F., the barometer being at 30 ins.

DRY MEASURE.

Cu. Yard.	Bushels.	Cu. Feet.	Pecks.	Gallons.	Cu. Ins.
1	21·0223	27	84·089	168·179	46656

·0036047	·014419	·028837	·11535	1

APOTHECARIES' MEASURES.

Gallon (C) = 8 pints (O) : 1 pint = 20 fluid ounces (oz. weight of water).
Ounce (f℥) = 8 drachms (f℈) = 480 minims (♏) = 720 drops (gtt).
One wine-glass = 4 tablespoonfuls = 16 teaspoonfuls = 2 ounces.
Symbols.—f. or fl., fluid ; ss., one half ; aa., for each. Thus, f℥ss. means ½ a fluid ounce.

Care should be taken to distinguish the difference between Stubs' Iron Wire Gauge and Stubs' Steel Wire Gauge. The former is commonly known as the English Standard Wire or Birmingham Wire Gauge, and designates the Stubs' *Soft* wire sizes.

The Stubs' Steel Wire Gauge is the one employed in measuring drawn steel wire or drill rod, of Stubs' make, and is also used by some makers of American drill rods.

(*Brown and Sharpe.*)

VARIOUS FOREIGN WE[illegible]D MEASURES WITH THEIR APPROX[illegible]BRITISH EQUIVALENTS.

(Compiled by the Boa[illegible]de (July 1923) from information published by the respective Governments.)

SECTION XLIV

PATENTS, TRADE MARKS, AND DESIGNS

(Contributed by a Chartered Patent Agent.)

SECTION XLIV

PATENTS, TRADE MARKS, AND DESIGNS.

(Contributed by a Chartered Patent Agent.)

PATENTS.

Application for a patent must be made by the inventor or inventors either alone or in conjunction with one or more co-applicants or a limited company. By inventor is understood either the actual inventor or a person who first introduces an invention from abroad or to whom an invention is communicated from abroad.

When an application is made it is accompanied by either a 'provisional' or a 'complete' specification. In the former case the specification must describe the nature of the invention, but need not particularly describe the same, and the applicant has the right to use and publish the invention during nine months from the date of application, which time may be employed in perfecting the invention and in applying for foreign patents. This protection against the consequences of use and publication is known as Provisional Protection. Should a complete specification not to be filed within the prescribed period of nine months, the application is deemed to be abandoned, and no official publication of the provisional specification takes place. When the application is accompanied by a complete specification, full protection is obtained from the date of the acceptance, and between this date and that of the sealing of the patent the applicant has all the privileges and rights accorded by the patent, except that he will not be entitled to institute any proceeding for infringement, unless and until a patent for the invention has been granted.

When a provisional specification has been filed and it is not desired to abandon the application, a complete specification must be filed within nine months from the date of filing the provisional specification; one month's extension of this time, however, can be obtained on payment of a fee. In such a case the complete specification must describe substantially the same invention as that the nature of which is disclosed in the provisional specification; if not, the Comptroller may require the complete specification to be amended to avoid any disconformity between the two specifications.

A complete specification—whether filed with the application or after a provisional specification—must fully describe (if necessary with the assistance of drawings) the manner of carrying out the invention in practice, and at the same time clearly and correctly point out the features of novelty by a distinct statement of the invention claimed. The complete specification on being filed is submitted to an examiner who makes an investigation to ascertain whether the invention described therein has been wholly or in part claimed or described in any specification (other than a provisional specification not followed by a complete specification) published before the date of the application, and deposited pursuant to any application for a patent made in the United Kingdom within fifty years next before the date of the application, or in the complete specification of any prior application, although such complete specification may not have been filed when the application was made. If any anticipating specifications are found, the applicant will have the opportunity of amending the specification, and, if the amendment is not effected to the satisfaction of the Comptroller, the Comptroller may insert a reference to any of the prior specifications in the specification by way of notice to the public. Where the Comptroller is satisfied that the invention has been wholly and specifically claimed, he may refuse to grant a patent.

When an applicant has two or more provisional applications running concurrently and the subject-matter of such applications is of such a nature as to constitute a single invention which may properly be covered by one patent, the Comptroller may accept one complete specification in respect of the whole of such applications and grant a single patent thereon bearing the date of the earliest of such applications; in case of legal proceedings, however, the respective dates of the several applications may be considered.

Patents of addition for improvements in, or modifications of, an invention already patented may be applied for for any unexpired term of the original patent, and no renewal fees, other than those payable in respect of such original patent, will be payable.

Great Britain is a party to the International Convention for the protection of industrial property, under which an applicant for a patent in any one of the States being parties to the Convention may obtain priority in any of the other States—that is to say, an application may be made in any such States, notwithstanding that publication of the invention may have been made therein, providing that such application be filed within twelve months from the date of the original application.

When a complete specification has been accepted such acceptance is advertised, and the specification will be open to public inspection. Notice of opposition to the grant of a patent may be given at any time within two months from the date of such advertisement, but on the following grounds only, viz.:—

(*a*) That the invention was obtained from the opponent or from a person of whom he is the legal representative.

(*b*) That the invention has been published in the complete specification of a British patent filed in the United Kingdom within fifty years before the date of application for the patent, the grant of which is being opposed, or has been made available to the public by publication in any document (other than a British specification) published in the United Kingdom prior to the application.

(*bb*) That the invention has been claimed in the complete specification of a British patent which, though not published at the date of the application for a patent, the grant of which is opposed, was deposited pursuant to an application for a patent which is, or will be, of prior date to such patent.

(*c*) That the nature of the invention or the manner in which it is to be performed is not sufficiently or fairly described in the complete specification.

(*d*) That the complete specification includes matter not in the provisional specification, and forms the subject of an application made by the opponent in the interval between the leaving of the provisional and complete specifications.

(*e*) That, in case of an application under the International Convention, the specification describes or claims an invention other than that for which protection has been applied for in a foreign state or British possession, and that such other invention forms the subject of an application made by the opponent in the interval between the leaving of the application in the foreign state or British possession and the leaving of the application in the United Kingdom.

If there is no opposition, or, in case of opposition, if the determination is in favour of the grant of a patent, the Comptroller causes a patent to be sealed.

The decision of the Comptroller in most cases is subject to appeal to the Law Officer.

Letters patent extend to Great Britain, Ireland, and the Isle of Man, and are granted for sixteen years, subject to the payment of renewal fees commencing at 5*l.* in respect of the fifth year, and increasing 1*l.* for each succeeding year during the term of the patent, the last payment being 16*l.* These renewal fees are payable before the commencement of the year in respect of which the payment is made, but extensions of time for making these payments up to three months can be obtained, with the addition of a fine, and in the event of a patent lapsing through the non-payment of a fee, the Comptroller is empowered to revive the patent on certain conditions.

At any time after the sealing of a patent the Comptroller may, if requested by the patentee, cause the patent to be endorsed with the words 'licences of right' and any person shall then be entitled, as of right, to a licence under the patent upon such terms as, in default of agreement, may be settled by the Comptroller.

Furthermore, any person interested may apply to the Comptroller alleging that there has been an abuse of the monopoly rights under a patent and asking for relief. Such rights will be deemed to have been abused, if, after four years from the date of the patent, the invention—being capable of being worked in the United Kingdom—is not being worked on a commercial scale; or if such working is being prevented or hindered by the importation from abroad of the patented article; or if the demand for the patented article is not being met to an adequate extent and on reasonable terms; or if trade or industry is being prejudiced by refusal to grant licences, or by conditions attached by the patentee to the purchase, or use of the patented article or to the working of the patented process. If the Comptroller is satisfied that an abuse of the monopoly rights has been proved, he may order the patent to be indorsed with the words 'licences of right' and grant a licence to the applicant on such terms as he may think expedient; or he may order the patent to be revoked.

For 'PATENT SPECIFICATION DRAWINGS,' see page 200.

TRADE MARKS.

Trade marks are registered under the Trade Marks Act of 1905 as amended by the Act of 1919, which provides that a registrable Trade Mark must contain, or consist of, at least one of the following essential particulars:—

1. The name of a company, individual, or firm represented in a special or particular manner.

2. The signature of the applicant for registration or some predecessor in his business.

3. An invented word or invented words.

4. A word or words having no direct reference to the character or quality of the goods, and not being, according to its ordinary signification, a geographical name or a surname.

5. Any other distinctive mark; but a name, signature or word or words, other than such as fall within the descriptions in the above paragraphs 1, 2, 3, and 4, shall not be registrable under the provisions of this paragraph except upon evidence of its distinctiveness.

Provision is also made for the registration of any special or distinctive word or words, letter, numeral, or combination of letters or numerals used as a Trade Mark by the applicant or his predecessors in business before the 13th August, 1875, and which has continued to be used down to the date of the application for registration.

The Trade Marks Act of 1905 as amended by the Act of 1919 provides for a new kind of registration of Trade Marks whereby certain marks, not registrable under the principal Act, can now be registered, provided they have been in *bona-fide* use in the United Kingdom for not less than two years. For this purpose the Register is divided into two parts called Part A and Part B, the new kind of marks being registered in Part B.

An application for registration is made on a form bearing the necessary stamp and should be accompanied by four additional representations of the mark properly mounted. The application is then examined and the mark compared with other marks on record in the Trade Marks Office (this provision may be dispensed with in the case of application to register in Part B), and if, in the opinion of the registrar, any mark or marks be found having such resemblance to the mark sought to be registered as to be calculated to deceive, the applicant will be notified of the conflicting mark or marks, and if, within one month from the date of issuing such notice, no action is taken by the applicant the application will be deemed to be abandoned. Should, however, the applicant so desire, the registrar will appoint a hearing in order that the applicant may attend before him, when the registrar will decide whether the application can proceed. Appeal can be taken from the decision of the registrar to the Board of Trade.

When an application is allowed the mark is advertised in the Official Journal of the Trade Marks Office. The application is then open to opposition for one month from the date of the Journal in which the advertisement appears, and should no opposition be entered the registrar will, upon payment of the registration fee, issue his certificate of registration.

The term of registration of a Trade Mark is fourteen years and may be renewed.

DESIGNS.

For articles which do not form the subject of a patent, protection may in some cases be obtained by design registration where the novelty consists of shape, pattern or ornamentation. Copyright is granted for five years and is renewable for a further similar term, and it is within the discretion of the Comptroller of Patents and Designs to extend the term of a copyright for a third period of five years.

SECTION XLV

COST OF ENGINEERING WORKS

(Contributed by John T. Rea, Author of 'How to Estimate.')

SECTION XLV

COST OF ENGINEERING WORKS.*

(Contributed by John T. Rea, Author of 'How to Estimate.')

AERIAL ROPEWAYS.

Two broad types—Single-rope or Monocable, and Double-rope or Bi-cable. In the former the load carriers hang from and move with an endless hauling wire rope, for gradients up to 1 in 4; in the latter the load carriers hang from a fixed wire rope (double line), and are drawn along with an endless hauling rope, for any gradient.

Aerial ropeways fixed complete, including wire ropes, pulleys, carriers, wooden supports, engine, driving gear, machinery, labour, etc., to carry 10 or 20 tons per hour, in loads not exceeding 5 cwts. per carrier, and gradients as above, pre-war costs :—

	Per Mile.
	£ £
Running single-rope system, to carry 10 tons per hour	900 to 1,200
" " " 20 "	1,400 „ 1,700
Fixed-rope system (double line), to carry 10 tons per hour	1,500 „ 2,500
" " " 20 "	2,200 „ 3,200

Prime Cost of Plant with Steel Structures.—The following table, by Mr. John H. Huntley, M.I.E.S., shows the pre-war standard amounts for aerial ropeways with no peculiar complications, using spiral construction ropes up to 20 tons capacity and locked coil ropes for 40 to 80 tons capacity, and represents the total cost of the plant erected. For lengths over 5 miles costs in proportion.

Capacity in Tons per Hour.	Length of Line in Miles.			
	½ Mile.	1 Mile.	2 Miles.	5 Miles.
Tons.	£	£	£	£
5 per hour	1,900	2,000	3,300	6,900
10 "	2,100	2,300	3,650	7,400
20 "	2,350	2,600	3,900	8,000
40 "	2,500	2,870	5,000	10,500
60 "	2,850	3,200	5,700	11,900
80 "	3,100	3,500	6,300	13,100

Working Costs per Day.—The following pre-war costs, by Mr. John H. Huntley, M.I.E.S., include depreciation, but exclude cost of driving, which varies extremely owing to the difference of height between stations, etc., and cannot be standardised.

Length in Miles.	Capacity per Day in Tons.					
	50 Tons.	100 Tons.	200 Tons.	400 Tons.	800 Tons.	1,000 Tons.
	s. d.	*s. d.*	*s. d.*	*s. d.*	*s. d.*	*s. d.*
½ mile	17 6	21 0	25 0	32 0	42 4	48 0
1 "	19 5	24 0	28 10	37 7	52 0	58 5
2 "	26 6	31 6	36 4	49 7	68 10	76 10
5 "	45 7	51 0	61 0	83 3	126 0	156 10

* All prices mentioned are pre-war figures unless otherwise stated; present rates (1928) about double.

Aerial Ropeway at Loch Leven, Argyllshire (1906).—Erected for the construction of a dar for water-power purposes. Length of line about 4¼ miles. Arranged on the single-rope systen and has a mean gradient of 1 in 22·8, or a difference in altitude of 1,100 ft. against the load Three bends in the line, with a station at each bend, and including the power station and bot terminals, there are six stations for loading and unloading. Eighty-six trestles, averaging 24 f high. Trestles, terminals, angle, and power stations of pitch pine. Driving power is from Pelton wheel of 250 brake horse-power. Speed of line, 300 ft. per minute. Capacity, 700 t 1,000 tons per day, with 580 steel buckets, each having an individual load of 6 cwt., an spaced about 90 ft. apart. Twenty men are engaged in working the line. Total cost, includin carriage, erection, and foundations, etc., complete, about 12,500*l.* or 2,600*l.* per mile.

Cost of operating per ton-mile, allowing for redemption in 3 years, labour and 10 per cen on the labour account for supervision, was estimated at 2*d.*

Plant for Single-rope Fixed-grip System.—Prices vary greatly according to the ground passe over and the material transported, so the following figures are merely approximate. They are th rates for articles at manufacturers' works to which must be added the cost of packing and markin for export, about 4 per cent. overall, carriage, loading and unloading, and erection with concret foundations, etc., as well as of motive power, which always differs. The value of timber structure would be about 15 per cent. less than that of corresponding structures in steel. From quotation received in August, 1922.

Description of Parts.	10 tons per 10 hrs'. line. £	25 tons per 10 hrs'. line. £	50 tons per 10 hrs line. £
1. Steel wire rope, trestle mountings, grips and carriers for a length not exceeding 1 mile—per mile	400	600	825
Ditto over 1 mile but not exceeding 3 miles in length—per mile	440	660	910
2. Driving and tension gears for a line not exceeding 1 mile	140	160	175
Ditto over 1 mile but not exceeding 3 miles in length	250	300	330
3. Mountings for each angle station giving any degree of deviation	70	80	90
4. Steel trestle structures, average about 16 per mile, height 20 ft., per trestle	18	22	20
5. Steel structures for terminal gears for a line not exceeding 1 mile	100	120	135
Ditto, ditto, for a line over 1 mile, but not exceeding 3 miles in length	160	180	200
6. Steel structures for angle stations, each	50	65	75

Example of Approximate Estimate.—To illustrate the method of estimating from the fore going particulars the following example is given. The cost of a ropeway ¾ mile long to carr 25 tons per 10 hours with one angle station: steel trestles, and timber structures for termina and angle stations. From quotations received in August, 1922:

	£	*s.*	*d*
Steel wire rope, trestle mountings, grips, carriers, as No. 1—¾ of 600*l.* per mile	450	0	0
Driving and tension gears as per No. 2	160	0	0
Mountings for angle station as per No. 3	80	0	0
Steel structures for 12 trestles as per No. 4—22*l.* × 12	264	0	0
Timber structures for terminal gears as per No. 5—120*l.*, less 15 per cent. (18*l.*)	102	0	0
Timber structures for angle stations as per No. 6—65*l.*, less 15 per cent. (9*l.* 15*s.*)	55	5	0
	1,111	5	0
Packing and marking for shipment, 4 per cent.	44	9	0
Total cost of ropeway materials for ¾ mile	1,155	14	0

Add to the foregoing carriage, unloading, erection, foundations, and motive power.

ARTESIAN WELLS.

Artesian bored tube wells, including boring by the percussion, percussion hydraulic, or rotary methods, according to the sub-strata, supplying steel-socketed lining tubes with butt ends flush-screwed, and special solid steel cutting shoe, and providing all materials, plant and labour, up to 100 ft. in depth; add 10 per cent. for every additional 10 ft. Telescoping the lining tubes

is obsolete, as they should be one continuous tier. Special sizes run up to 4 ft. and 6 ft. diameter. See also 'Tube Wells' p. 2877.

Soil.	Tubes.	Per ft. deep.
In easy soils, such as earth and sand .	3 in. to 4 in. external diameter . .	8*s.* to 10*s.*
	6 in. „ 9 in. „ „ . .	13*s.* „ 18*s.*
In soft rocks, such as chalk or shale .	3 in. „ 4 in. „ „ . .	11*s.* „ 13*s.*
	6 in. „ 9 in. „ „ . .	17*s.* „ 23*s.*
In hard rocks, such as basalt or sandstone	3 in. „ 4 in. „ „ . .	17*s.* „ 20*s.*
	6 in. „ 9 in. „ „ . .	25*s.* „ 32*s.*

London.—The charges of the Metropolitan Water Board for domestic supply are based upon 5 per cent. of the rateable value of property, and in the case of a large building, such as business premises or a bank, are out of all proportion to the water used. Charges of 200*l.* to 600*l.* per annum are common, and even 4,000*l.* has been paid. Roughly speaking, any building owner in London paying more than £120 a year for water will find it better to sink an artesian well. Boreholes over 1,000 ft. deep have been sunk in the London basin, and yield 100,000 gallons per hour. The flow is reliable, the water is of a low temperature, pure and soft (generally about 5° of hardness compared with 16° of the Water Board supply), leaves no deposit on pipes and boilers, and the cost is very small.

The capital outlay for many important buildings in London for an independent water supply, including sinking an artesian well and providing the pumping plant, where the quantity runs from 1,000 to 4,000 gallons per hour, varies from 1,500*l.* to 4,000*l.*

The cost of pumping artesian wells depends on the lift and power required, and may be as low as ¼*d.* per 1,000 gallons on a lift up to 400 ft., and is commonly 1½*d.* per 1,000 gallons for manufacturing purposes. Pumping by electric motors, with current at 1½*d.* per unit, will work out to about 2½*d.* per 1,000 gallons when the water is raised some 300 ft. from the borehole to the storage tanks above. The capital invested in a separate installation would thus be repaid in three to six years, leaving only the pumping costs to be considered as an annual expense, so that the value of artesian wells is apparent.

BORING.

Percussion boring by the ordinary 'English' method to depths of 500 ft. costs 10*s.* to 20*s.* per foot, advancing 2 to 6 ft. per 24 hours.

Rope boring for oil, salt, etc., holes 6 to 15 ins. diameter, 20 to 60 ft. per day, costs 2*s.* to 8*s.* per foot. Plant for a hole 2,000 ft. deep weighs 80 tons, and costs about 2,000*l.*

Diamond boring in hard rock, 5 ins. diameter, costs in this country 8*s.* per foot down to 500 ft., and 12*s.* to 18*s.* down to 1,500 ft. Advance 5 to 10 ft. per day. Bort 'diamonds' are 2*l.* to 3*l.* per carat for the softer rocks, and carbon 6*l.* to 12*l.* per carat for the harder ones. Boreholes above 6 ins. diameter are thus almost prohibitive for expense.

Chilled shot method for relatively large boreholes, 6 in. diameter, in hard ground, costs 10*s.* to 12*s.* per foot. It is slower but cheaper than diamond boring, and consists of chilled steel shot fed into a thick steel pipe notched at the lower end and rotated upon the rock to be pierced, with water forced down.

Actual Costs—The following are from practical pre-war experience :—

	Per ft. *s.* *d.*
Rope boring at Middlesbrough, 8 ins. diameter, to depths of 1,000 ft., at rate of 60 ft. per day	8 0
Ditto. in Pennsylvania and Ohio, 6 to 15 ins. diameter, at rate of 20 ft. per day, average contract price	6 0
Diamond boring in Scotland, 5 ins. diameter, to depth of 1,800 ft., advancing about 6 ft. per day	6 4
Ditto. in British Columbia, 2,200 ft. deep, at rate of 10 ft. per day	8 6
Ditto. in Nova Scotia, 2 ins. diameter, sunk by the Government in fairly hard ground to depths of 200 to 400 ft. in 1913, averaged	9 0
Ditto. in Victoria, also sunk by the Government, averaged in the coal measures in 1912	9 3
Ditto. ditto. in the harder rocks	14 0
Chilled shot 6 in. Government boreholes in Nova Scotia in 1913, averaged . . .	10 6
Some important boreholes of the world—	
Bezuidenville, Transvaal, 5,800 ft.	42 0
Czachow, Rybnik, Upper Silesia, 7,350 ft.	43 4
Paruschowitz, Silesia, 6,572 ft. (12 in. bore decreasing to 2¾ in.)	11 6
Schladebach, Prussia, 5,737 ft.	21 2

BREAKWATERS.

Breakwaters formed of large rough blocks of stone as a foundation with heavy masonry walls above, forming a harbour. Average width 300 ft., and average depth 50 ft. below low-water mark. 150*l.* to 300*l.* per foot run complete.

Alderney.—Composite type of rubble mound and upright wall above. Mound terminate 12 to 15 ft. below low water. 338 ft. wide at base and 36 ft. at top. 90 ft. mean depth of wate 259*l.* per foot run.

Algiers.—Mound type, with large random concrete blocks surrounding the rubble. 50 f mean depth of water. 122*l.* per foot run.

Bizerta.—Composite type, with wall built on caisson system. 58 ft. mean depth of wate 60*l.* per foot run.

Colombo.—South-west breakwater, 1874–85, is 4,212 ft. long, built of concrete blocks weighin 18 to 30 tons, on the sloping bond system, and cost 705,200*l.*, or 167*l.* per foot run. Extension t ditto as a further protective arm, 1907–12, is 1,800 ft. long, also of concrete blocks, and cos 380,000*l.*, or 211*l.* per foot run.

North-east breakwater, 1894–7, is 1,100 ft. long, and constructed as a rubble embankment the north-west or island breakwater, 1900–6, is 2,657 ft. long, and made of concrete; the tw together cost 500,000*l.*, or 133*l.* per foot run.

Total length of the four breakwaters about 9,770 ft., with five lighthouses on them, and tota cost 1,585,200*l.*, or an average of 162*l.* per foot run. Depth of sea, 30 to 36 ft. at low water. Ris of tide at Ceylon is only 2 ft. Engineers, Sir John Coode, Son, and Mathews.

Dover.—Wall type, composed of concrete blocks weighing 26 to 40 tons, 82 ft. wide at base an 40 ft. at top. Depth of water, 61 ft. high; 42 ft. low. 415*l.* per foot run.

Holyhead.—Composite type, with very predominant mound of rough rubble stone, 400 f average width at base and 40 ft. at top. Sea and harbour walls built upon the mound. 54 f mean depth of water. 163*l.* per foot run.

Marseilles.—Mound type. Outer casing of concrete blocks, 25 tons each, and average thickne 14 to 20 ft. Inner casing of rubble stone, 2 to 5 tons weight, about 12 ft. thick. Rubble hear ing, ½ to 2 tons stones, and 6 ft. thick. 35 ft. mean depth of water. Joliette section, 72*l.* per fo run, and new section, 109*l.* per foot run.

Naples.—Composite type. 93 ft. mean depth of water. 186*l.* per foot run.

Plymouth (1811–48).—Rubble mound with walls on top, nearly a mile long. Slope of 5 to seawards. 360 ft. wide at base and 43 ft. at top. Average depth, 45 ft. below low-water mar Absorbed 3,670,440 tons of rubble and 22,150 cubic yards of masonry. Engineer, Sir Joh Rennie. 250*l.* per foot run.

Portland.—Mound type with large rubble blocks and heavy masonry wall above, 270 ft. wi at base. The largest of its kind in England and in two portions—inner about 2,000 ft. long ar outer over 6,000 ft., with 400 ft. opening between them. Depth of water, 58 ft. high; 51 f low. 6 million tons of stone used. Convict labour. Total cost, 1,250,000*l.* 140*l.* per foot ru

Maintenance.—This is less for walls than for rubble mounds, as the latter are greatly affect by wave action, and need constant repair. Cost varies according to situation and exposur and rarely exceeded 1*l.* per foot run per annum, pre-war. For some time it averaged 1*s.* 3 at Holyhead, 7*s.* at Geneva, and 13*s.* at Naples.

(See Section XXVIII, p. 1519.)

BRIDGES.

Types.—(1) Arched, (2) Cantilever, (3) Girder or lattice, (4) Movable (bascule or liftin rolling, swing, and transporter), (5) Pontoon (with barrels, boats, planks, etc.), (6) Suspensio (7) Trestle (with very high steel or wood framework piers), and (8) Viaducts or "land" bridges.

Costs include foundations, piers, abutments, approaches, footpaths, machinery, etc., complet

Description.	Span.	Number of Spans.	Cost per ft. sup.
	ft. ft.		
Brick or masonry	50 to 100	Single	£1 to £2
	50 „ 100	Multiple	£2 „ £4
Ordinary concrete	30 „ 50	Single	15*s.* „ £1
	30 „ 50	Multiple	£2 „ £3
Reinforced concrete	50 „ 100	Single	10*s.* „ £1
	50 „ 100	Multiple	£1 „ £2
Steel bascule or lifting	50 „ 100	Single	£3 „ £5
	100 „ 200	Multiple	£5 „ £8
Steel girder or lattice	50 „ 100	Single	£1 „ £3
	50 „ 100	Multiple	£2 „ £5
Steel suspension	50 „ 100	Single	£1 „ £2
	100 „ 200	Multiple	£2 „ £4
Steel swing	50 „ 100	Single	£2 „ £3
	100 „ 200	Multiple	£3 „ £5

Brooklyn Bridge (1870–83).—Wire cable suspension bridge over the East River, connecting New York with Brooklyn. 5,990 ft. total length, including 1,596 ft. central span from tower to tower, two spans of 930 ft. from the towers to anchorage on either side, and the approaches of ironwork and masonry, 1,563 ft. on New York side and 971 ft. on Brooklyn side. Width 85 ft., divided into five passage ways for vehicles, trams, and foot passengers. Clear height above high water 135 ft. in centre and 118 ft. at towers, giving a free passage to shipping. Towers 277 ft. above high water, upon rock foundation 80 ft. below surface of river and 40 ft. beneath its bed. Supporting the spans are four cables nearly 16 ins. diameter, and 3,758 ft. long, with anchorages of solid stone masonry weighing 60,000 tons each, and rising 90 ft. above river's edge. Each cable contains 5,282 galvanised steel wires in 19 separate strands, of 278 lengths, and each strand has over 200 miles of continuous wire. Wires laid parallel, not twisted, with spiral wire wrapping. Deflection of cables between towers is 128 ft. Engineer, John A. Roebling. Total cost, including approaches, 3,100,000*l.*, or 518*l.* per ft. run, or 6*l.* per ft. sup.

Forth Bridge, Scotland (1883–90).—At South Queensferry, near Edinburgh. Steel latticework, with two main cantilever spans 1,710 ft. each, and 24 land spans, 42 to 688 ft. each. Each cantilever 690 ft. long, united by a girder 250 ft. span. The steel towers supporting the cantilevers are 361 ft. high, and the steel tubes of both are 12 ft. diameter at base, tapering to extremities. 50,960 tons of steel employed and 6½ millions of rivets. Complete length, 8,100 ft., and with approaches, 8,300 ft.; width, 30 ft.; 145 acres of surface to be painted. Double line railway. Height of railroad, 152 ft. above high water. Main piers of masonry, and concrete foundations in rock, 70 ft. below high water. Central pier of granite standing on the islet of Inchgarvie. Engineers, Sir John Fowler and Sir Benjamin Baker. Contractors, Sir Wm. Arrol & Co. Total cost, including approaches, 1,700,000*l.*, or 25*l.* per ft. run, or 7*l.* per ft. sup.

Gôkteik Viaduct (1901).—In the Shan States, Upper Burmah, the viaduct forming part of the railway where it crosses a deep wide valley about 80 miles from Mandalay, and runs on to Kunlon at the Chinese frontier. The second most lofty steel trestle bridge in the world, but for combination of height, length, and weight of material easily the first. It is straight for 1,638 ft. at the centre, with terminal curves of 800 ft. radius, 341 ft. and 281 ft. long respectively. Total length between abutments, 2,260 ft. There are 15 trestles or skeleton towers, varying from 250 ft. to 320 ft. in height, 10 spans of 120 ft., and 7 spans of 60 ft., or 17 spans altogether, formed with lattice or plate girders. 5,000 tons of metal, and 200,000 rivets. All the metal parts, some 230,000 pieces, were prepared in the United States, shipped 10,600 miles, and transported 460 miles up country by the Burmah railway, where they were re-assembled and put up without a hitch. A single track was first laid, but space was left for a second when the traffic required it. Total cost, 61,000*l.*, or 27*l.* per ft. run, or 3*l.* 10*s.* per ft. sup.

Holyhead, Britannia Tubular Bridge (1845–50).—Across the Menai Straits. Continuous double tube of wrought-iron plates, each tube 15 ft. wide by 23 ft. high at ends, and 30 ft. at centre, with one railway line in each. Two main spans of 460 ft. each, two smaller spans of 230 ft., and two shore spans of 65 ft., or a total length of 1,510 ft. Each tube weighs 4,680 tons, and is fixed 100 ft. above high water. Two abutments, and three masonry piers or towers, the highest of which is 230 ft. Complete distance, with approaches, 1,560 ft. Engineers, Robert Stephenson, assisted by Sir Wm. Fairbairn and Professor E. Hodgkinson. Total cost, including approaches, 608,000*l.*, or 390*l.* per ft. run, or 13*l.* per ft. sup.

Kingston Bridge, Surrey (1825–8).—Brick and stone. Five elliptical arches: middle arch 60 ft. span, other arches 56 ft. and 52 ft. span. Ratio of piers to spans, 1: 6. Bridge, 382 ft. long and 25 ft. wide. Bridge itself, 26,800*l.*; approaches and other works, 13,200*l.* Total cost, 40,000*l.*, or 105*l.* per ft. run, or 4*l.* per ft. sup.

London Bridge (1824–31).—Stone bridge of five elliptical arches over the Thames and of handsome design, connecting the City of London with the borough of Southwark, and replacing the 12th century stone bridge. Centre span 152 ft., rising 30 ft. above Trinity high-water mark, arches on each side 140 ft. spans, and abutment arches 130 ft. Total length 1,005 ft., and 56 ft. outside width. Two centre piers 24 ft. thick, exterior stones of granite and interior half Bramley Fall and half Painshaw, Derbyshire; granite voussoirs. General depth of foundations 30 ft. below low water. Engineer, John Rennie, and completed by his son Sir John Rennie. Contractor's tender for the bridge alone was 425,081*l.*, but actual cost was 1,458,310*l.*, or 1,451*l.* per ft. run, or 26*l.* per ft. sup.

Newcastle High-level Bridge (opened 1849).—Example of a true bowstring arch in which there is no cross bracing, with six spans of 125 ft. each. Total length 1,373 ft., and 37 ft. external width. Superstructure is supported on five intermediate piers and eight land piers, four at each side, latter with arched abutments. Height of soffit above high-water, 83 ft. Arched ribs of cast iron and ties of wrought iron. 4,728 tons of cast iron and 321 tons of wrought iron were employed. A carriage roadway passes underneath the railway, the bridge supporting both. Engineer, Robert Stephenson. Total cost, 243,000*l.*, or 177*l.* per ft. run, or 5*l.* per ft. sup.

Newport Bridge, Mon. (1924-27).—Over the river Usk. Reinforced concrete and stone, five spans, length 356 ft., and overall width between parapets 60 ft. Two footways. Total cost, 140,300*l.*, or 6*l.* 11*s.* per ft. sup. of deck area.

Niagara Suspension Bridge (1852–5).—Connects the United States with Canada. A wire-rop suspension bridge for road and railway, with a single span of 821 ft., centre to centre of pier and 245 ft. above the water. Superstructure is a hollow rectangular box, 24 ft. wide × 18 ft deep, on the top of which the railway is laid, while the bottom forms a roadway for public traffic both floors being constructed of timber beams, etc. Railway floor is suspended from two wir cables, 10 ins. diameter, at intervals of 5 ft., and the lower floor by two similar cables. 120 stays Two masonry towers at each end of the bridge, 60 ft. high, 15 ft. square at base, tapering t 8 ft. square at top, and pierced by an arch. Anchor chains embedded in masonry 7 ft. × 3 ft. and 25 to 35 ft. deep. Engineer, John A. Roebling. Total cost, 80,000*l.*, or 97*l.* per ft. run or 4*l.* per ft. sup. This suspension bridge was replaced by a steel arch bridge in 1897.

Tower Bridge, London (1890–4).—Steel, with two fixed shore suspension spans 270 ft. each, an a lifting central span of 200 ft. Two large steel towers encased with stone, with two bascules o drawbridges in the centre and connected at top by a high-level footbridge, 140 ft. above high wate Bascules weigh 1,000 tons each, and are raised and lowered by hydraulic machinery which i contained in the chambers of the piers supporting the towers, each pier being 180 ft. long × 70 ft wide. Staircases and hydraulic lifts are provided in the towers for foot passengers crossing the high level bridge when the bascules are raised for the passage of shipping. Complete length, wit approaches, 2,980 ft. Width of fixed spans between parapets, 60 ft., and breadth across centr span 50 ft. Engineer, Sir John Wolfe Barry. Sir Horace Jones, the City Architect, designe the architectural details. Contractors: Sir John Jackson for foundations; Sir Wm. Arrol & Co for steelwork; and Sir W. G. Armstrong & Co. for hydraulic machinery. Total cost, includin machinery and approaches, 903,000*l.*, or 303*l.* per ft. run, or 5*l.* per ft. sup.

Westminster Bridge, London (1853–62).—Road bridge over the Thames, with cast and wrough iron arches of 120 ft. span and 20 ft. high. 1,160 ft. long and 83 ft. wide. Engineer, Thoma Page. Contractors, Messrs. Marc. Total cost, 235,000*l.*, or 203*l.* per ft. run, or 2*l.* per ft. sup.

Suspension Bridges.

Estimated costs by a well-known firm of steel manufacturers of strong steel wire rope suspensio bridges of large power, designed to carry 15-ton traction engines with wagons in line on th bridge floor, the prices being for the whole of the iron and steel work, including lattice pie surmounted by cast-iron saddles for the ropes to run over, all bolts and nuts, holding down bolt steel rod suspenders, open-steel parapets, high tension steel cables, steel cross girders to suppo decking, steel wind ties under floor, etc., ungalvanised but painted two coats before despatch delivered f.o.b., London or Liverpool, or to railway stations in England; supplied only, an exclusive of timber floor, foundation work, and erection. Pre-war rates. If a concrete asphalt floor is required the prices will be subject to an increase, owing to the additional strengt necessary and the greater weight put on the structure. The span is centre to centre of pier and the feet super. for area unit price, have been reckoned accordingly.

Span.	Width.	Area.	Total Price.	Price per Foot Super.	Weight of Steelwork.
Ft.	Ft.	Ft. Sup.	£	*s.* *d.*	Tons.
50	19	950	565	11 11	31
75	19	1,425	785	11 0	44
100	19	1,900	945	9 11	53
125	19	2,375	1,115	9 5	60
150	19	2,850	1,275	8 11	66
175	19	3,325	1,430	8 7	75
200	19	3,800	1,575	8 3	81
225	19	4,275	1,740	8 2	91
250	19	4,750	1,880	7 11	100
275	19	5,225	2,065	7 10	110
300	19	5,700	2,230	7 10	118

The prices may therefore vary from about 8*s.* to 12*s.* per ft. sup. If erected complete, includir timber floor and concrete, stone, or brick foundations or abutments, and anchorages, the cos would be at least double the foregoing. Narrower bridges, down to 3 ft. wide, for lighter load such as foot traffic, cattle, mules, horses and carts, would be of reduced construction an correspondingly cheaper.

Actual costs of steel wire-rope suspension bridges, delivered and erected, including steel pier wire ropes, suspension bands, and timber for floor, but exclusive of any foundation work

anchorages. Pre-war rates. The span is centre to centre of piers, and the feet super. for area unit cost have been reckoned accordingly as before.

Locality.	Load.	Span.	Width.	Area.	Total Cost.	Cost per F.S.
		Ft.	Ft.	Ft. Sup.	£	s. d.
Bournemouth, across Alum Chine	Donkey carts and bath chairs	230	6	1,380	590	8 7
Derby sewage works	Foot traffic	86	3	258	165	12 9
Dryburgh, across the Tweed, near Melrose Abbey	Foot traffic	260	6	1,560	540	6 11
Linley, over the Severn. Two approach spans in addition, making a total span of 390 ft.	A row of 10-ton carts	213	12	2,556	1,700	13 3
Llandilo	Foot traffic	144	5	720	220	6 1
Llangollen	Foot traffic	146	3	438	190	8 8
Rhayader, for the Birmingham Corporation Waterworks	Cart traffic	110	10	1,100	450	8 2
Shrewsbury. Two approach spans of 30 ft. each in addition, making a total span of 210 ft.	Light vehicular traffic	150	8	1,200	950	15 10
Swalwell, over the Derwent	Foot traffic	125	4½	562	285	10 2
Warrington	Foot traffic	183	6	1,098	430	7 10
Wrexham, across the Dee.	Row of loaded haycarts	130	10	1,300	670	10 4

The average rate was therefore about 10*s.* per ft. sup. If erected complete, including foundation work and anchorages, the costs would be at least double foregoing.

Bridges of Concrete.

Coulouvrenière Bridge, Geneva (1895–6).—Across the Rhone, 351 ft. wide, and total length of bridge over the abutments 492 ft. Width between parapets 61 ft. 4 ins., two footways 12 ft. 6 ins. each, with a carriageway 36 ft. 4 ins. between the kerbs. Two large arches with spans 131 ft. 3 ins., and rise of 17 ft. 6 ins. Arches 3 ft. 3 ins. thick at both springings and centre, about 4 ft. 6 ins. at the haunches, and steel pivoted. Two smaller arches, 35 ft. 5 ins., and 39 ft. 4 ins., but are not pivoted, being elliptical. Very handsome bridge. Arches, spandrels, 9 spandrel walls, 2 ft. thick, 12 in. top table, and filling, all of concrete, 1 to 4¼, 6, 7, and 8. Piled abutments. Facing of spandrel walls, columns, cornice, and parapet of stone. Wooden centres were used, with sand boxes for adjusting and striking. Total cost, 68,000*l.*, or 138*l.* per ft. run, or 2*l.* 5*s.* per ft. sup. of roadway and footpaths. Cost per cubic yard, including centering and scaffolding, was 3*l.* 2*s.* 3*d.*

Eyach Bridge, Hohenzollern (1895).—Designed by Herr Max Leibbrand, of Sigmaringen. A single span of 98 ft. 5 ins., with a rise of 9 ft. 10 ins. Concrete arch and table, 1 to 7½, and foundations to abutments, 1 to 9, which are piled. Pivots or joints made of granite instead of iron or lead. Bridge is 143 ft. long, 12 ft. 6 ins. total width, with roadway 7 ft. 6 ins. wide, and each footpath 2 ft. 6 ins. The footpaths overhang the arch on either side and were formed of old iron rails. Plain iron railing as parapet. Cost, 900*l.*, or 6*l.* per ft. run, or 10*s.* per ft. sup.

Kirchheim Bridge, Württemburg (1897).—Over the Neckar, which is 361 ft. wide at this point, with 230 ft. of foreshore, or a total of 591 ft. Designed by President von Leibbrand, chief engineer to the State of Württemburg. Length of bridge from outside to outside of abutments, 592 ft., and space between parapets 17 ft. 8 ins., including road, 12 ft. 8 ins., and two footways, 2 ft. 6 ins. each ; open iron parapets. Four spans of concrete arches, 124 ft. 8 ins. each, with a rise at the centre of 18 ft. Thickness of arch at crown, 2 ft. 8 ins., increasing to 3 ft. at springing. Concrete piers 7 ft. 6 ins. thick at springing level, faced with stone at water level ; cutwaters also faced with stone. Concrete in arches and abutments, 1 to 7½, spandrel walls, tables, etc., 1 to 9, and foundations for piers, 1 to 4. Concrete on face was tooled and coloured, and concrete in piers rendered 2 ins. thick with 1 Portland cement and 2 sand. Lead joints in the centres and springings of arches 6 to 7 ins. wide, bedded and recessed in stone. Screw jacks were used for striking the centres in place of folding wedges or sand boxes. Cost, 7,000*l.*, or 12*l.* per ft. run, or 13*s* .5*d.* per ft. sup. of bridge table. Approaches, 2,250*l.* in addition.

Munderkingen Bridge, *Württemburg* (1893).—Over the Danube. Designed by President von Leibbrand. One span only of 164 ft., and rise 16 ft. 5 ins. Thickness of arch at centre 3·28 ft., at springing 3·61 ft., and at haunches 4·26 ft. The first concrete bridge where steel pivots on bearing boxes were used, one set at each abutment and one set at the crown. Internal and external spandrel walls, abutments, horizontal and intermediate tables, cornice, and arch itself, were of concrete, 1 to $7\frac{1}{2}$, and tinted. Spandrel face of limestone, and ornamental open iron parapet. Cost of bridge, including piled abutments, 3,600*l.*, or 21*l.* per ft. run, or 13*s.* 6*d.* per ft. sup. of road and footway surface. Approaches, 1,000*l.* in addition.

Neckarhausen Bridge, *Hohenzollern* (1900).—Over the Neckar. Designed by Herr Max Leibbrand, of Sigmaringen. The handsomest concrete bridge in Germany, the concrete being coloured, and no stone used. A single concrete arch of 164 ft. clear span, with a rise of 15 ft. Arch ring 2 ft. 10 ins. thick at the centre, 3 ft. at the springing, and 4 ft. at the haunches. The arch is tapered on plan, being 1 ft. 8 ins. wider at the springing than at the centre. Concrete spandrel columns and arches over, instead of solid spandrel walls and haunches, thus reducing both material and dead load. Arches pivoted with steel pins and cast-iron brackets or bearings, and those carrying roadway were strengthened with iron rails built into the top and abutments. Concrete in arch 1 to $7\frac{1}{2}$, faced with $\frac{3}{8}$-in. spalls of limestone. Voussoirs, cornice, etc., were coloured. Width of macadam roadway 13 ft., and overhanging footpaths 2 ft. 6 ins., which is a cheap method. Centering was supported on temporary piles, with screw jacks for striking. Cost, 3,000*l.*, or 17*l.* per ft. run, or 19*s.* 5*d.* per ft. sup. Long approaches, 5,000*l.* in addition.

Bridges of Reinforced Concrete.

Spans, 50, 75, or 100 ft. External width, including parapets, 25 ft. Height, from mean water level to underside of elliptical arch, 13 ft. 15*s.* to 30*s.* per ft. sup.

Items.	Cost.		
	50 ft. Span.	75 ft. Span.	100 ft. Span.
	£	£	£
Excavations	70	111	184
Concrete	251	462	667
Centering	129	240	341
Reinforcing Steel	104	194	277
Preliminaries 10 per cent.	55	100	147
Contractors' Profit, etc., 15 per cent.	91	166	242
Total Cost	700	1,273	1,858

Alexandra Bridge, *Pietermaritzburg* (1914–15).—Reinforced concrete on the Kahn system 170 ft. long × 30 ft. wide between the parapets, with two 5-ft. footpaths cantilevered over a 20-ft. roadway. Central arch 75 ft. span, and a half arch 38 ft. span at each end. Cost, including 5 per cent. for designs and supervision, 5,906*l.* for the bridge and 4,008*l.* for the approaches = 9,914*l.* total. 52*l.* per ft. run, or 2*l.* per ft. sup.

Brivio Bridge, *Italy* (1913–17).—Over the river Adda, and gives access to the railway station of Cisano Bergamasco. Entirely constructed of reinforced concrete, 444 ft. long and 30 ft. wide, with a 24 ft. roadway flanked by two raised footpaths, each 2 ft. 7 ins. wide, with edges of L irons. The roadway is about 26 ft. above the average level of the river, and suspended from three reinforced concrete arches overhead. Span of centre arch 177 ft., and of side arches 144 ft., all being supported on two massive concrete pillars and shoulders, each 43 ft. × 13 ft., built on a group of 48 steel-shod concrete piles made on the Considère system, 14 ins. square, and driven 43 to 53 ft. through the bed of the river by a steam hammer weighing 4 tons. Normal load on each pile averages 35 tons, uniformly distributed by a superimposed concrete slab 3 ft. thick. Foundations protected by pitch pine shuttering 5 ins. thick. Sole of roadway 5 ins. thick, covered with asphalt and a layer of concrete and gravel on top, with 12 in. × 30 in. transverse beams underneath attached to 11 in. × 24 in. vertical bars and to 18 in. × 40 in. longitudinal external beams. Cast steel rollers for expansion. Parapet is of cast ironwork. Bridge designed to carry a double-track electric tramway, a steam roller of 22 tons, and a dense crowd of people calculated at 10 cwt. per square yard. Total cost, 20,000*l.*, or 45*l.* per ft. run, or 30*s.* per ft. sup.

Chatellerault Bridge, *France* (1900).—Across the river Vienne, and is formed entirely of ferro-concrete on the Hennebique system. Centre span 164 ft. and two side spans 135 ft. each, with rises of respectively 16 ft. and 13 ft., and a width between the parapets of 26 ft. 3 ins., excluding two cantilevered footways which overhang 3 ft. 5 ins. Spans of four arched concrete ribs, 35 ins. deep × 19 ins. wide at springings, tapering to 9 ins. square at the soffit, and extrados connected together by an arched table. Roadway and footpaths supported by spandrel pillars, 8 ins. square, and longitudinal concrete beams, the top table being 10 ins. thick at the centre, tapering to 5 ins. at kerb. The bridge only weighs 250 lbs. per ft. sup. Cost, 8,000*l.*, or 18*l.* per ft. run, or 12*s.* 6*d.* per ft. sup.

Loughor Bridge, Glamorganshire (1920–23).—Spans the tidal estuary of the river Loughor, and replaces the old timber trestle structure. The new bridge is of reinforced concrete, from a design by Messrs. L. G. Mouchel and Partners, carried out by the Yorkshire Hennebique Contracting Co., Ltd. Length, 720 ft. between the abutments, divided into 18 spans of 40 ft. each. Width, 36 ft. between the parapets, providing two footways, 5 ft. wide, and a carriage-way of 26 ft. between the kerbs. Piers rest on reinforced concrete piles, 15 ins. square, driven into the bed of the river to various depths of 5 ft. to 37 ft. Four piles to each pier, each pile being encased in a reinforced concrete cylinder, 1 ft. 9 ins. diameter, cross-braced with reinforced concrete tie-beams, 10 ins. × 14 ins. Main longitudinal beams, 12 ins. wide × 2 ft. 8 ins. deep in the centre; secondary beams, 7 ins. × 18 ins. Four main or longitudinal beams and 12 secondary or cross beams to each span. 5½ ins. reinforced concrete decking, covered with 2 ins. cushion of sand and finished with 4 ins. of 'Tarmac' roadway. Ducts, 18 ins. × 9 ins., left under footpath concrete flagging to accommodate electric cables. Parapet of pierced concrete panels, with moulded handrail. Abutments have reinforced concrete wall supporting the ground behind. Steel reinforcement was of plain round steel bars, ⅜ in. to 1⅛ in. diameter, and the bridge was built in half-widths, so as not to interrupt the traffic. It was designed to carry a normal working super. load of 120 lbs. per square ft., and a rolling load of 48 tons. Total cost, excluding approaches, 56,700*l.*, or 79*l.* per ft. run, or 2*l.* 2*s.* 7*d.* per ft. super.

Pontypridd Bridge (1908).—Over the river Toll. Reinforced concrete on the Hennebique system, with the two piers on reinforced concrete piles. Total length 170 ft., and width 30 ft. Central river span 117 ft. Total, 3,600*l.* 21*l.* per ft. run, or 14*s.* per ft. sup.

Terralba Bridge, Italy (1916).—Part of a scheme for enlarging the Genova Brignole Station. It replaces about 600 ft. of the Terralba highway connecting St. Martino with St. Fruttuoso. Total length of bridge, including approaches, is 750 ft.; width 45 ft., including two footways each 5 ft. wide. Constructed of reinforced concrete and has six spans, four of 61 ft. and two of 58 ft., each span being built in three bays across. Part of the inclined approach was also formed in six spans, each of 35 ft. and three bays across, the remainder of the plane being constructed of massed work between supporting walls. Subsoil was a deep bed of soft, marshy clay, which prohibited piling and required a specially light foundation formed by 1 per cent. reinforced concrete rafts, the reinforcement being carried up into the pillars of the bridge. The rafts were supported on two pinewood piles per square yard, each 20 ft. long by 10 ins. wide, and tops coated with cement. Volume-ratio of reinforcement in superstructure was 1·8 per cent. to the gravel concrete. Total cost, 18,000*l.*, or 24*l.* per ft. run, including approaches, or 12*s.* 5*d.* per ft. sup. of concrete, including the foundation, and 6*s.* 8*d.* per ft. sup. of road and footpath.

Warrington Bridge (1913).—Over the river Mersey. Largest single-span reinforced concrete bridge in England, on the Considère system. River walls and abutments also of reinforced concrete. Clear span 134 ft., width 80 ft. between parapet walls, and ten parabolic ribs supporting upright and cross beams on which rest 6½ in. floor slabs. Roadway has wood-block paving, and footpaths have concrete slabs. Total cost, including approaches, 24,000*l.* or 34*s.* per ft. sup. ditto.

CANALS.

The total length of canals for inland navigation in the United Kingdom is 4,673 miles (3,641 in England and Wales, 184 in Scotland, and 848 in Ireland). 1,144 miles are owned by the railway companies, and 219 controlled by them. An ordinary inland canal in this country is 25–30 ft. wide at bottom, 40–45 ft. wide at water level, and 4–5 ft. deep. Canal boats are 70–75 ft. long and 7–8 ft. wide; barges are about the same length, but double the width, *i.e.* 14–15 ft. For maps and towns, etc., see the *Handbook on Canals*, with map, issued by the Canal Control Committee (Board of Trade), and obtainable from H.M. Stationery Office, Kingsway, London, W.C. 2, price 6*d.* net, or 8*d.* post paid. (November, 1918.) Total paid-up capital was 47,550,000*l.*, and the cost varied from about 5,000*l.* to 20,000*l.* per mile.

In 1905 the constructional cost of new canals in Great Britain, 40–45 ft. wide at bottom, 80–85 ft. wide at water level, and 8 ft. deep in centre, with locks 230 ft. × 22 ft. and 6½ ft. draught of water over sills, suitable for two lighters of 250 tons carrying capacity, was estimated at 30,000*l.* per mile. The cost of improving existing routes to reach the same standard was similarly reckoned at 15,000*l.* per mile.

In France, in 1870, there were 3,000 miles of canals and 2,000 miles of canalised rivers. The average cost of the French canals up till then was 11,600*l.* per mile, and of the canalised rivers, 4,800*l.* per mile. Present length, 7,500 miles.

BARGE OR BOAT CANALS.

Basingstoke Canal (1794–96).—From Basingstoke, Hampshire, to the river Wey Junction Canal, Surrey. Length, 37 miles, including 29 locks. Total cost, constructional works only, 170,000*l.* or 4,600*l.* per mile.

Bridgewater Canal (1759–61).—In Lancashire; originated by the Duke of Bridgewater to bring coal from his mines on the Worsley estate to Manchester, but it was later extended to the Mersey. First length was only 10 miles, but complete length 38 miles. 50 ft. wide and 5½ ft. deep, with vertical stone walls instead of banks. The Barton aqueduct carried the canal over the river Irwell, at a height of 39 ft. Engineer, James Brindley. (The Bridgewater Canal was purchased by the Manchester Ship Canal Co. in 1887.) Total cost, constructional works only, 235,000*l.*, or 6,180*l.* per mile.

Dortmund and Ems Canal (1890–1900).—From Dortmund to the North Sea at Emden. Part of the 157 miles total length includes canalisation of the river Ems. Bottom width, 59 ft., 98 ft. at water level, and depth, 8 ft. Works include 1 canal lift, 3 masonry aqueducts, 185 bridges, and 20 masonry locks, 220 ft. long each. Artificial canal portion cost 29,000*l.* per mile, and river canalisation portion, 14,000*l.* per mile. The locks were 15,000*l.* each, and the weirs 8,500*l.* each. Total cost, 3,970,000*l.*, including 400,000*l.* for land.

Cost per mile of total length, including land	25,286*l.*
,, ,, ,, ,, constructional works only	22,740*l.*

Elbing Canal.—In Holland. Length, 28 miles. Total cost about 212,200*l.*, or 7,580*l.* per mile.

Grand Junction (begun, 1790).—From the Oxford Canal at Bramston, Northamptonshire, to the Thames at Brentford, Middlesex. Width at bottom, 24 ft., and 36 ft. at water level. The main line is 93 miles long, but the total length, with branches, is 140½ miles (189 by Whitaker). Cost per mile, including land, etc., 19,500*l.*

Ulster Canal (1826–41)—Unites Lough Neagh with the upper Lough Erne, and extends from Charlemont, Co. Armagh, on the river Blackwater (which is navigable from Charlemont to Lough Neagh), passes Caledon, Monaghan, and Clones, and joins Upper Lough Erne, Co. Fermanagh, near Belturbet. Length, 47 miles. Total cost, constructional works only, 200,000*l.*, or 4,255*l.* per mile.

Worcester and Birmingham Canal (1791).—Connects these towns, and joins the Severn at the former. Runs through a tunnel 500 yards long, and three shorter tunnels. All are 18½ ft. wide, 7 ft. deep, and 18 ft. high. Length, 30 miles. Original cost per mile, 20,000*l.*

Irrigation Canals.

For irrigating large tracts of land for growing cotton, rice, sugar, wheat, etc., especially in America, Australia, Egypt, and India. The cost varies according to geographical features, nature of ground, available water supply, size of main canal, number of branches, distributing channels, and subsidiary works. In India the costs are approximately—

5,000*l.* to 10,000*l.* per mile of canal and main branches.
2*l.* to 3*l.* per acre of land irrigated.

Agra Canal (opened 1874).—In India, and draws its water supply from the Jumna at Okhla, ten miles below Delhi, irrigating 380,000 acres. The main and branch canals total 110 miles, and the distributing channels 600 miles. Total cost, including all works, 800,000*l.*

7,270*l.* per mile of canal and main branches.
2*l.* 2*s.* per acre of land irrigated.

Cavour Canal (begun 1862).—In Italy, and starts from the river Po, not far from Turin, and terminates in a junction with the river Tessin above Novara. Length, 51 miles, with a total fall of 71 ft. The summer discharge of the Po being found insufficient, a branch canal was constructed for bringing a supplementary supply from the Dora Baltea, which rises from the glaciers of the Alps and possesses a large discharge in the summer when the Po is low. Total cost, 4,104,000*l.*, or 80,470*l.* per mile of main canal.

Ganges Canal (opened 1854).—The largest irrigation work in India, and waters the district between the Ganges and the Jumna. Designed by Sir Proby Cautley. The canal with its main branches is about 650 miles long, and can irrigate an area of 1,205,000 acres. It was remodelled about twelve years later. Total cost up to 1878 was 3,055,000*l.*

4,700*l.* per mile of canal and main branches.
2*l.* 11*s.* per acre of land irrigated.

Lower Ganges Canal (1870–90 approximately).—An extension to supplement the original foregoing canal. Designed for a total length of 582 miles. Irrigates 2,500,000 acres. Total cost about 4,500,000*l.*

7,730*l.* per mile of canal and main branches.
1*l.* 16*s.* per acre of land irrigated.

Upper Swat Canal.—In India, along mountainous country at the Malakand hills. Length, 150 miles, and irrigates 450,000 acres. Works include a tunnel, 11,235 ft. long by 18 ft. wide and 13 ft. high, seven shorter tunnels totalling one mile, 167 aqueducts across ravines, 20 to 100 ft. deep, a weir 700 ft. long, stop-dam, pitched channel, etc. Total cost about 1,300,000*l.*

8,670*l.* per mile of canal and main branches.
2*l.* 18*s.* per acre of land irrigated.

Ship Canals.

Large waterways as formed for ocean-going shipping, complete with channels, locks, docks, machinery, entrance breakwaters, etc.; construction works only, and excluding promotion, purchase of land, compensation, or legal charges:

100,000*l.* to 500,000*l.* per mile of actual canal.

Amsterdam Canal (1865–76).—Connects Amsterdam and the Zuyder Zee with the North Sea *via* Lake Y and Wyker Meer, and across a narrow neck of sand-hills in a westerly direction. Works comprise a dam 4,462 ft. long, with maximum bottom width 147 ft. and top width 13 ft., shutting off Lake Y from the Zuyder Zee. There are five large locks, six sluiceways, three swing-bridges (two railway and one roadway), and a harbour of 260 acres at the North Sea entrance, protected by two rubble stone breakwaters, 5,070 ft. long each, with pier on top formed of concrete blocks, 6 to 12 tons each. Canal is 16½ miles long, 88½ ft wide at bottom, 186 ft. at water level, and 23 ft. deep (now increased to 30 ft.). 21,000,000 cubic yards of soil and mud were excavated and dredged and 13,000 acres of land reclaimed. The sale of the latter realised about 70*l.* an acre, or a total of some 910,000*l.*, which mitigated the engineering cost. The largest type of dredger used could deposit 1,300 cubic yards of material on the banks in twelve hours, at 2*d.* per cubic yard. Permanent pumping machinery was installed for draining the adjacent lands into the canal and out again into the sea. Engineers, Sir John C. Hawkshaw and Mr. Dirke. Contractors for the whole of the works, Messrs. Henry Lea and Son. For full details see paper by Mr. Harrison Hayter read at the Institution of Civil Engineers in 1880, and printed in the *Proceedings*, vol. lxii. p. 1.

	Total.	Per Mile.
Constructional works only . . .	2,600,000*l.*	157,580*l.*
Other expenditure and charges . .	400,000*l.*	24,240*l.*
Whole cost	3,000,000*l.*	181,820*l.*

Caledonian Canal (1803–23).—From Inverness to Fort William, along the Great Glen of Scotland, and connects Inverness Firth with Loch Eil, having Lochs Ness (22 miles), Oich (6 miles), and Lochy (10 miles) in between. The summit level of 102 ft. is overcome by 28 locks, 14 on either side, each about 170 ft. long × 40 ft. wide; 23 miles of artificial or canal navigation in four stages, and 38 miles of natural lake navigation through the foregoing three lochs, the total distance between extremities being thus 61 miles. Canal is 50 ft. wide at bottom, 120 ft. at water level, and 17 to 20 ft. deep, for vessels up to 600 tons burden. Engineer, Thomas Telford. Total cost, including land, 1,311,270*l.*, or 57,010*l.* per mile of actual canal length of 23 miles.

Corinth Canal (1882–93).—Across the isthmus of Corinth, between Gulf of Corinth and Gulf of Aegina, in Greece, and mostly through solid rock with very deep cutting. The neck of land rises in the centre to 286 ft. above the bottom of the canal. Bottom width, 72 ft., and average depth, 26 ft. No locks. Length, 4 miles. Entrances at each end protected by solid jetties built out into the sea. Greek engineer, Matsos. Total cost, 1,400,000*l.*, or 350,000*l.* per mile.

Cronstadt and St. Petersburg Canal (1877–90).—Starts from the Neva and goes south-west for about 2 miles, when it curves and proceeds in a straight line to Cronstadt. Average width, 240 ft., and depth, 20 ft. No locks. Total length, 16 miles, including 10 miles bay channel and 5 miles canal proper. Costs per mile are based on the total length of 16 miles.

	Total.	Per Mile.
Constructional works only . . .	1,240,000*l.*	77,500*l.*
Other expenditure and charges . .	760,000*l.*	47,500*l.*
Whole cost	2,000,000*l.*	125,000*l.*

Elbe and Trave Canal (opened 1900).—In Germany. Width at bottom, 72 ft., and depth, 10 ft. Length, 41 miles. Total cost, 1,170,000*l.*, or 28,540*l.* per mile.

Kiel Canal (1888–95).—Also known as the Kaiser Wilhelm Canal, or the Baltic and North Sea Canal, connecting Kiel in the Baltic to Elbe in the North Sea. Mostly through marshes or shallow lakes and river valleys, with tidal waterway throughout. Original dimensions: bottom width, 72–85 ft., surface width, 190–226 ft., and depth, 28–30 ft. (since increased to 150 ft., 335 ft.,

and 45 ft., respectively). Total excavation, 106,000,000 cubic yards. Two entrance locks, originally 492 ft. long × 82 ft. wide × 32 ft. deep over sill (now enlarged to 1,083 ft. × 148 ft. × 45 ft., and constructed in concrete, each lock having three pairs of caissons dividing the chambers into lengths of 725 ft. and 330 ft.). The original canal was completed in 1895, and the works for broadening and deepening in 1914. Breakwaters at each end. Length, 61 miles.

	Total.	Per Mile.
Original cost up to 1895, including land purchase	7,800,000*l.*	127,870*l.*
Enlargements and reconstructions up to 1914	11,200,000*l.*	183,605*l.*
Whole cost	19,000,000*l.*	311,475*l.*

Manchester Canal (1887–94).—Connects Manchester with Eastham, the Mersey port of Liverpool. Fifteen miles of canal proper, and 21 miles tidal waterway, or 36 miles total. Canal averages 120 ft. wide at bottom, 170 ft. at water level, and 26 ft. minimum depth (now increased to 28 ft.). Four sets of locks, with an average lift of 15 ft. each, thus raising the water level of the canal at Manchester to 60 ft. above mean sea-level at Liverpool. Capacity for 9,000 ton vessels, and it takes seven hours to pass through the whole distance and locks. The latter vary from 600 ft. × 80 ft. to 150 ft. × 30 ft., and sills 16–28 ft. deep below normal water-level of canal, the gates being moved by hydraulic machinery. The works include 160 acres of docks, with warehouses, machinery, and 95 miles of railway sidings, 6 high-level bridges, 7 swing-bridges, and the Barton swing aqueduct, 234 ft. long, for the Bridgewater Canal over the Irwell (to replace Brindley's fixed aqueduct), which latter canal had to be bought. 52,000,000 cubic yards of excavation and removal. Plant cost 980,000*l.*, and comprised engines, locomotives, steam pumps, cranes, piling machines, horses, wagons, temporary railway, etc. Principal engineer, Sir E. Leader Williams, assisted by W. Henry Hunter and others. Contractors, T. A. Walker (who died on November 25, 1889, during the progress of the work), and his executors, T. J. Reeves, L. P. Nott, and C. H. Walker, who continued. For full particulars see *History of the Manchester Ship Canal*, 2 vols., published by Sherratt & Hughes, 34 Cross Street, Manchester. Price 25*s.* Details of cost below are based on the total length of 36 miles:—

	Total.	Per Mile.
Purchase of Bridgewater Canal	1,783,000*l.*	111,438*l.*
Land and compensation	1,167,000*l.*	72,937*l.*
Constructing the canal and docks	9,000,000*l.*	562,500*l.*
Interest on capital during construction	1,050,000*l.*	65,625*l.*
Law charges, Parliamentary expenses, etc.	500,000*l.*	31,250*l.*
Whole cost	13,500,000*l.*	843,750*l.*

Average annual maintenance per mile of canal	2,000*l.*
Do. do. per acre of docks	400*l.*

Panama Canal (1904–15).—From Colon, on the Atlantic, to Panama on the Pacific. A concession was granted in 1876 to a French syndicate, which made surveys for two years and reported to an international congress at Paris in May, 1879. The Panama Canal Company was then floated, with Ferdinand de Lesseps as president, and preparatory work undertaken in 1881, the first excavation being made in January, 1882. The French scheme, however, was finally abandoned in 1904 owing to fever and bad administration, after the failure of both the first and a second company, and after only 12 miles had been cut out of the 54 originally proposed, and 50,000,000*l.* spent. On May 4, 1904, the United States Government bought the effects of the French company in Panama for 8,000,000*l.*, and started the American project as now completed. A strip of territory extending five miles on each side of the route of the canal was also purchased from Colombia for 2,000,000*l.* Colonel (now General) George W. Goethals, U.S.A. Engineers, was chairman of the Canal Commission which worked out the type and salient features.

Total length along axis, 50½ miles, but only 41½ miles within the coastlines. Rise of tide at Limon Bay in the Atlantic varies from 7 to 19 in., and from 8 to 21 ft. at Panama. The opening channel at sea-level, from Limon Bay to Gatun, is 7 miles long by 500 ft. wide and 41 ft. deep. At Gatun are three twin locks to raise vessels to the summit canal level, 85 ft. above sea, also an earthen dam, 8,000 ft. long, 1,500 to 2,000 ft. thick at the base, 100 ft. wide at top, and 115 ft. high, damming the Chagres River and forming the artificial Gatun Lake, 164 square miles area, with surface 85 ft. above sea-level, through which ships pass in a channel 500 to 1,000 ft. wide and 45 ft. deep. After 23¼ miles of Gatun Lake the Gaillard Cut (formerly Culebra Cut) extends for 8 miles and 280 ft. maximum depth, with a channel 300 ft. wide and 45 ft. deep. Then a single twin lock, with 30 ft. drop, at Pedro Miguel to the small Miraflores Lake, where a channel, 1½ miles long by 500 ft. wide and 45 ft. deep, leads to Miraflores itself. Here two twin locks lower vessels, 31 ft. each lock, to the Pacific sea-level, and a channel 8 miles long, likewise 500 ft. wide and 45 ft. deep, conducts them to deep water in Panama Bay. In addition there are nearly 3 miles in locks and alongside approach walls. About 26 miles are artificial canal work, out of the total distance of 50½ miles.

Width of channel varies from 300 to 1,000 ft. at bottom, and depth 40 to 45 ft. The six pairs of locks are 1,000 ft. long × 110 ft. wide, with intermediate gates to divide them into two sections of 600 ft. and 400 ft., and 6 pairs of lock gates with steel frames and plates. There are 46 pairs of lock gates altogether, 46 to 82 ft. high, and the largest weighs 730 tons. Least depth of water over sills of locks when lake is at normal level is 41 ft.

The total excavation for the whole canal amounted to 220,000,000 cubic yards (130,000,000 in the dry, and 90,000,000 by dredges), of which about 112,000,000 yards was in the Culebra Cut, the most extensive excavation ever made. Concrete in the locks came to 4,500,000 cubic yards. Maximum number of employees at one time was 50,000 (6,000 Americans, 5,000 Europeans, and 39,000 negroes).

In addition to General Goethals, other engineers were Messrs. S. B. Williamson, chief of the Pacific Division, Gaillard, Sibert, Hodges, Goldwork, Schildhauer, Cornish, Zinn, Nichols, Alfred Noble, and others.

The canal was opened for traffic on August 15, 1914, the steamer passage being 10 hours each way. Ships are towed by electric cars or 'mules' running on rails alongside the waterway. Several landslides subsequently occurred necessitating temporary suspension of traffic till well into 1915.

Total cost was approximately as follows, the cost per mile being based on the total length of 50½ miles:—

	Total.	Per Mile.
Spent by the original French Canal Co. up to 1904 before abandonment	50,000,000*l.*	990,100*l.*
Purchase money paid to the French Canal Company	8,000,000*l.*	158,416*l.*
Sum paid to the Republic of Colombia or Panama for concession	2,000,000*l.*	39,604*l.*
Constructional cost of American scheme, including terminal facilities	65,000,000*l.*	1,287,130*l.*
Whole cost	125,000,000*l.*	2,475,250*l.*

Saulte Ste. Marie Canal (opened 1895).—In Canada, connecting Lakes Superior and Huron, Known as the 'Soo,' and passes 20,000 vessels a year round the Saulte Ste. Marie Falls. Length, 1½ miles. Width at bottom 142 ft., and depth 20 ft. It has the longest lock in the world, with gates operated by electric power. Total cost, 560,000*l.*, or 509,090*l.* per mile.

Suez Canal (1859–69).—Between Port Said on the Mediterranean and Suez on the Red Sea. M. Ferdinand de Lesseps, engineer and promoter. Total length all but 100 miles, including 60 miles through the shallow lakes of Menzaleh, Ballah, Timsah, and the Bitter Lakes, with and without dredging, and the rest actual canal formed by cutting. Sandy soil and a little rock. Sixty dredging machines were employed, and about 100,000,000 cubic yards of material excavated and dredged. Over 25,000 labourers were employed during the earlier period. Canal was originally 72 ft. wide at bottom, 196 to 328 ft. at water-level, and 16 ft. average depth (now increased to 147 ft., 420 ft., and 39 ft., respectively). No locks, as the canal is level throughout. Rise of tide is only about 1 ft. in the Mediterranean, and 6 ft. in the Red Sea. A slight current of 3 ft. per second keeps the canal clear. Passage takes 16 hours.

An auxiliary freshwater canal was constructed at the same time from the Nile, near Cairo, to Lake Timsah, and thence nearly parallel to the main canal as far as Suez, to supply fresh water and to convey provisions and materials, and afterwards to irrigate. It was 26 ft. wide at bottom, 56 ft. at surface, and 6½ ft. deep.

At Port Said the harbour encloses 450 acres, with an eastern breakwater 6,233 ft. long and a western breakwater 9,800 ft., composed of random concrete blocks weighing 20 tons. At Suez the outlet of the canal is protected on the south-west by a mole 2,900 ft. long, and on the north-west by a sold earthwork embankment.

Costs per mile are based on the total length of 100 miles.

	Total.	Per Mile.
Cost of promotion and preliminaries	5,300,000*l.*	53,000*l.*
Constructional works only	10,700,000*l.*	107,000*l.*
Enlargement, widening, and deepening since 1869.	4,000,000*l.*	40,000*l.*
Whole cost	20,000,000*l.*	200,000*l.*
Less indemnity granted in 1864 for loss of forced labour, about	4,000,000*l.*	40,000*l.*
Net cost	16,000,000*l.*	160,000*l.*

Welland Canal (opened 1833).—Constructed to avoid the break in communication between Lakes Erie and Ontario, Canada, caused by the falls in the Niagara River, and runs parallel to the latter on the west. Length, 26 miles. Twenty-seven locks, with total lift of 330 ft. Enlarged in 1867 to accommodate vessels of 400 tons. Again enlarged, 1874–87, to take vessels of 1,000 to 1,500 tons, so that the bottom width of canal would be 100 ft., and depth 14 ft. Locks increased to 270 ft. long by 45 ft. wide, and 14 ft. depth of water on the sills.

	Total.	Per Mile.
Cost of original canal opened in 1833	2,700,000*l.*	100,935*l.*
Cost of enlargement from 1874–87	2,300,000*l.*	86,019*l.*
Whole cost	5,000,000*l.*	186,954*l.*

(See p. 1578.)

Concrete.

(*London Prices, July*, 1927.)

The following prices are based on best British Portland cement at 64*s.* per ton to contractor delivered on site, including use of bags and returning empties. Clean pit sand 13*s.* per yard cube, Thames ballast 10*s.* 6*d.*, gravel 13*s.*, and 1½ in. broken stone 14*s.*, ditto. Wages, labourer, 1*s.* 4½*d.* per hour.

The rates for measured work include materials, measuring and mixing by hand, wheeling up to 20 yds., laying and ramming, and 17 per cent. establishment charges and profit. Machine-mixed concrete would be about 4*s.* to 6*s.* per cubic yard cheaper.

Plain Concrete.

		s.	*d.*
Portland cement concrete, 1 to 6, with unscreened Thames ballast in foundations, walls, and masses exceeding 12 ins. thick	per yd. cube	39	0
Ditto, 1 : 3 : 6, with 1 cement, 3 sand, and 6 clean pit gravel, ditto	,,	41	0
Ditto, 1 : 3 : 6, with 1 cement, 3 sand, and 6 local broken stone, 1½ in. gauge graded down to ¼ in., in foundations, walls, and masses	,,	45	0
Add if in foundations and walls not exceeding 12 ins. thick	,,	3	0
Add if in underpinning in short lengths up to 5 ft.	,,	7	0
Add if executed between high and low water mark, including covering with canvas to protect against tides	,,	8	0
Deduct from the foregoing 1 : 3 : 6 proportions if the proportion is 1 : 4 : 8	,,	3	0
Portland cement concrete, 1 : 3 : 6, with 1 cement, 3 sand, and 6 clean pit gravel, spade finish, spread and levelled in beds, pavings, or ground floors, 6 ins. thick	per yd. sup.	7	6
Add for floated or trowelled surface with 1 cement and 2 sand, ¾ in. thick	,,	2	2
Granitic surface layer of 1 cement to 2 granite chippings, 1 in. thick, floated and trowelled to a smooth face whilst concrete is unset	,,	4	6
Hard dry filling under concrete, of clean broken brick, hard core, mason's spalls, etc., spread and levelled 6 ins. thick	,,	2	9
Portland cement concrete, 1 : 3 : 6, with clean pit gravel, ballast, or crushed aggregate, graded ¾ in. to ¼ in. gauge, cast *in situ* complete, with exposed faces left clean and perfect, including use of casings, for kerbs and channels to footpaths, roads, pavements, etc.	per ft. cube	2	3
Ditto pre-cast solid building blocks, exceeding 4 ins. thick, and set in 1 to 3 cement mortar	,,	3	0
Ditto pre-cast hollow blocks (measured as solid), ditto, ditto	,,	2	6
Ditto pre-cast lintels, door and window heads, window sills, steps, copings, cornices, quoins, and setting and jointing in 1 to 3 cement mortar	,,	4	0

Reinforced Concrete.

Reinforcement varies from ½ to 5 per cent. sectional area of the steel compared with the sectional area of the concrete, according to position.

1 per cent. volume of steel = 132 lbs. reinforcement per yard cube of concrete.

General economy of reinforced concrete construction for large structures, and over steel-framed buildings of equal strength, is 10–20 per cent., and over brick buildings and in heavy foundations 20–30 per cent.

Reinforced concrete factories, offices, stores, warehouses, etc., cost 10*d.* to 1*s.* 2*d.* per ft. cube.

Proportionate costs vary : ⅛ concrete, ⅓ steel, ⅓ formwork, to ½, ½, ¼, respectively.

General proportions—1 : 1½ : 3 and 1 : 2 : 4. Cement should equal British Standard Specification (B.S.S. No. 12). Ferrocrete, Super-Cement, and Ciment Fondu harden much more quickly and are stronger, but more expensive.

Sand graded $\frac{3}{16}$ in. to $\frac{1}{16}$ in. (75 per cent. to pass ¼ in.), and aggregate ¾ in. to $\frac{3}{16}$ in. Concrete to be quickly deposited in layers not exceeding 6 ins. thick and 3 ins. next reinforcing bars, and in quantities not more than 2 ft. cube, closely punned round the steel.

Each class of work and story to be given separately, and heights stated. The space occupied by the steel is not to be deducted. Prices for mass concrete include forming chamfers, splays, rounded angles, etc., but the use of moulds for these should be taken under formwork.

The concrete, the steel, and the formwork are first priced separately, then combined into a condensed table of complete work.

Concrete Piles—

		s.	d.
Pre-cast reinforced Portland cement concrete, 1 : 1½ : 3, with 1 cement, 1½ washed sand, and 3 local broken stone, ¾ in. or ⅝ in. gauge graded down to $\frac{3}{16}$ in., in bearing or sheet piles, including all moulds, and planted in position ready for driving (exclusive of steel reinforcement and pile shoes)	per ft. cube	6	0
Steel reinforcement and shoes for ditto, and fixing	,,	4	0
Placing and driving ditto not less than 144 sq. ins. section, including all working apparatus, such as pile engine, etc., in ordinary ground (portion in soil only to be measured)	,,	4	0
Ditto ditto ditto in tide work	,,	6	0
Ditto ditto if driven from barges or floating stages, including use of same	,,	3	0
Simplex reinforced concrete piles, 16 ins. diameter, cast in place and driven complete (8 or 10 piles, of 25 ft. average length and reinforcement provided, can be driven per 8-hr. day)	per ft. run	12	0
Allowance for bringing, erecting, and removing pile engine and tackle for driving, etc.	per job	10*l.* to 20*l.*	

Concrete Foundations, Walls, etc.—

		s.	d.
Reinforced Portland cement concrete (only), 1 : 2 : 4, with 1 cement, 2 washed sand, and 4 local broken stone, ¾ in. gauge graded down to $\frac{3}{16}$ in., in foundations and masses	per yd. cube	52	0
Ditto in walls exceeding 12 ins. total thickness	,,	56	0
Ditto beams, not exceeding 72 ins. sectional area, to floors or roofs	per ft. cube	2	3
Ditto large beams, exceeding 72 ins. but not exceeding 144 ins., ditto	,,	2	1
Ditto independent piers, columns, struts, or pilasters	,,	2	6
Ditto steps, stairs, winders, strings, carriages, etc., any section	,,	2	9
Ditto floor slabs or flat roofs, 4 ins. thick, and hoisting 30 ft.	per yd. sup.	6	9
Ditto ditto ditto 6 ins. thick, ditto	,,	10	2
Ditto walls, 6 ins. thick, measured between piers or projections	,,	1	8

Steel Reinforcement—

		s.	d.
Mild high-tension steel in accordance with B.S.S. No. 15, British Standard Specification for Structural Steel, Class A, in plain reinforcement (round, square, or flat bars), including cutting, bending, hoisting, 30 ft., assembling or putting into position, stout binding wire, and fixing complete in foundations, walls, columns, floors, etc., in			
¾ in. to 1½ in. bars	per cwt.	20	6
⅞ in. to ⅝ in. ,,	,,	21	6
¼ in. to ⅜ in. ,,	,,	23	0
Steel in proprietory systems of trussed or stirrup bars, and fixed	,,	27	0
Ditto ditto indented, twisted, or studded bars, ditto	,,	30	0
Fixing only sheet reinforcement, such as expanded metal, fabric, and mesh systems, 4–16 lbs. per yd. sup., including cutting, bending, or wiring (measured net, with no allowance for laps)	per yd. sup.	0	6

Formwork—

		s.	d.
Use and waste of 1½ in. simple flat centring, machine-planed one side, edges shot, to flat concrete floors and roofs, including about 14 ft. cube rough timber supports, ties and braces, and wedges, cleats, clamps, dog-irons, straps, etc., erection, cutting, maintenance, striking, and removal, average 12 ft. high	per square	50	0
Ditto ditto if to curved ceilings or roofs	,,	60	0

		s.	d.
Use and waste of 1 in. to 1½ in. strong shuttering to concrete walls, vertical or battering, including all supports, struts, etc., erection, cutting, maintenance, and removal (both sides measured)	per square	55	0
Ditto ditto if curved	,,	65	0
Add if boarding is machine-planed one side, thicknessed, and edges shot	,,	5	0
Limewashing internal surfaces of formwork, or treating with soft soap or mould oil, to prevent the concrete adhering	per yd. s.	0	3
Use and waste of fir in rough timber supports, shoring, etc.	per ft. cube	3	0
Use and waste of casing, planed one side and edges shot, to concrete beams, average 12 ins. × 6 ins., including sides and soffits	per ft. sup.	1	0
Ditto to concrete pillars or columns, square, including supports	,,	0	10
Ditto ditto ditto circular, ditto	,,	1	0
Use and waste of casing in narrow widths, under 12 ins., to openings in concrete walls, floors, roofs, etc	per ft. run	0	8
Extra for fillets to internal angles of casing or shuttering to form chamfers, splays, rebates, rounded angles, etc., not exceeding 9 ins. girth	,,	0	4
Labour forming small splays, grooves, rounded edges, etc., not exceeding 2 ins. girth	,,	0	2
Raking, cutting, and waste to shuttering, not exceeding 1½ ins. thick	,,	0	3

Complete Work.—The following may give a general idea of the whole cost, including concrete, steel reinforcement, and formwork, but there are so many systems that it is impossible to be more definite, and the range of values must be great :—

			s.	d.
Reinforced concrete	12 ins. × 12 ins. piles, including driving, etc., complete	per ft. run	12 to	18
,, ,,	12 ins. pillars or columns, square or circular	,,	6 ,,	12
,, ,,	steps, stairs, and sills, average 12 ins. × 6 ins.	,,	4 ,,	8
,, ,,	floors, 4 ins. to 6 ins. thick, including beams	per yd. sup.	15 ,,	30
,, ,,	flat roofs, 4 ins. to 6 ins. thick, including beams	,,	15 ,,	30
,, ,,	walls, 4 ins. to 6 ins. thick, vertical or battering	,,	12 ,,	24
,, ,,	partitions, 2 ins. to 4 ins. thick, smooth on both sides	,,	10 ,,	16
,, ,,	foundations, thick walls, and masses	per yd. cube	80 ,,	120

Reinforced Granite Concrete Tubes.

Manufactured by John Ellis & Sons, Ltd., 16 Pocklington's Walk, Leicester, of best Portland cement and Mountsorrel granite, 1 to 3, crushed, washed, and passed through ¼-in. mesh, and with sufficient sand to fill up all interstices. The tubes are made both with and without steel ribs, the latter being ¼ in. welded steel rings placed in the centre of the material, 12 ins. apart. The concrete is cast in vertical steel moulds, filled in thin layers, and rammed with a heavy machine-driven hammer. The pipes are left in the moulds for three days, after which they are put in the open air to mature for six months.

Prices of reinforced circular sewer tubes free on rail at works, Barrow-on-Soar, L.M.S. Railway (July, 1927) :—

Internal Diameter.	Thickness in inches.	Stock Lengths.	Weight per ft. run.	Feet per ton.	Price of Tube per ft. run.
ins.	ins.	ft.	lbs.	ft.	s. d.
12	1¼	3	56	40	2 6
15	1½	2 and 3	86	26	3 0
18	1½	2 ,, 3	97	23	3 6
21	1¾	2½ ,, 3	132	17	4 6
24	2	2 ,, 3	176	12⅝	6 0
27	2	2 ,, 3	199	11¼	7 0
27	2¼	2 ,, 3	219	10¼	8 0
30	2¼	2 ,, 3	276	8⅛	9 3
33	2½	3	289	7¾	10 0
36	2½	3	326	6¾	11 0
36	2¾	2 and 3	345	6½	12 0
39	3	3	415	5⅔	14 0
42	3	2 and 3	472	4⅝	16 0
45	3¼	3	541	4⅛	18 0
48	3½	2 and 3	640	3½	20 0
57	4½	3	943	2⅜	31 6
60	5	3	1120	2	37 6

Laying.—Cost of laying and jointing in addition. The tubes are usually laid on a square concrete bed raised half-way up the outside, and 6 ins. thick. The ogee joints are sealed with cement mortar, 1 to 1.

Connections.—Bends, junctions, circular manholes, well tubes, etc., are also supplied of granite concrete.

Other Tubes.—Socket and spigot sewer tubes, 15 ins. to 24 ins. diameter, and egg-shaped tubes, with internal measurements 18 ins. × 12 ins. to 60 ins. × 40 ins., are similarly made.

Stanton-Hume Reinforced Concrete Pipes.

The Stanton-Hume Reinforced Concrete Pipe is manufactured by the Stanton Ironworks Co., Ltd., near Nottingham, under sole licence from the Hume Pipe and Concrete Construction Co., Ltd., London. A hard, dense pipe is produced, owing to the centrifugal action of the moulding machinery, and the concrete mixture spreads itself evenly over the inner surface, while the circular motion expels excess air and water, so that there are no voids. All materials are mechanically tested in laboratories, then carefully graded and mixed by special apparatus, and the sand automatically washed. The pipe is particularly suitable for drainage and sewage work, as it is very strong, the internal surface is abnormally smooth, owing to the longer lengths fewer joints are required, and cost is low. The reinforcement is a spirally wound steel wire cage of great tensile strength, kept in a central position by centrifugal tendency.

The pipes are made 4 ins. to 60 ins. diameter, and in classes A, B, C, D, E, for working pressures of 10, 25, 50, 75, 100 lbs. per sq. in. respectively. Proportions, 1 : 2 and 1 : 3 graded granite, finely crushed.

Prices delivered 50 miles from Stanton Gate at Ilkeston, near Nottingham (July, 1927) :—

Internal Diameter.	Thickness in inches.	External Diameter.	Stock Lengths.	Weight of Pipe for Class A.	Weight of Collar A.	Price of Pipe per ft. run.
ins.	ins.	ins.	ft.	lbs.	lbs.	*s.* *d.*
4	1	6	6	104	13½	0 9
6	1	8	6	146	17	1 1
9	1⅛	11¼	6	237	26	1 9
12	1⅜	14⅝	6	380	40	2 9
15	1½	18	6	513	56	3 8
18	1⅝	21⅛	8	887	75	4 8
21	1¾	24½	8	1,111	92	5 9
24	1⅞	27¾	8	1,350	118	7 6
27	2	31	8	1,612	132	8 9
30	2⅛	34¼	8	1,906	175	10 6
33	2¼	37½	8	2,220	202	12 3
36	2⅜	40¾	8	2,540	240	15 0
42	2½	47	8	3,110	302	20 0
48	2¾	53½	8	3,900	415	25 0
54	3	60	8	4,790	560	32 6
60	3	66	8	5,310	620	38 6

Joints.—The above prices include one collar for each length of pipe. Pipes with ogee joints 5 per cent. less. Jointing requires skilled labour, but experienced men can be sent ; 1 cement to 2 sand.

Laying.—Cost of laying and jointing extra to rates in table. Reinforced bends, tees, angle branches, etc., are also made.

Deep-water Quays.

The structural conditions of deep-water quays are so variable that the assumption of a unit of cost is misleading. For ocean-going shipping in the Thames, however, the rates between 1919–22 (post-war) varied from 50*l.* to 200*l.* per ft. run.

Deep-water Quay, Greenhithe (1919–21).—On the south bank of the river Thames, and was an extension of the existing wharves of the Empire Paper Mills. Tidal range over 18 ft., with 17 ft. depth at low-water ordinary spring tides. Length of new section of the approach 455 ft.,

with minimum width of 8 ft., and new deep-water berthage at end 303 ft. by 52 ft. width throughout, and three splays at corners. Total deck area of new works approximately 24,600 sq. ft. Quay carried out in creosoted Oregon and pitch pine, with steel superstructure. Engineers, Messrs. Carey and Latham.

Total cost, 70,783*l.*, or 2*l.* 17*s.* 7*d.* per ft. sup. of new wharf accommodation obtained. About 93*l.* per ft. run, including approaches.

Deep-water Quay, Shellhaven (1920–21).—On the Essex side of the river Thames, and consisted of the extension of a deep-water berthage for an oil storage depot. Tidal range 18 ft., with 29 ft. depth at low-water ordinary spring tides. Length of new quay approach 560 ft. by 18 ft. wide, and new deep-water berthage at end 420 ft. long by 40 ft. deck width, the two forming a T shape. Total deck area approximately 31,000 sq. ft. All of reinforced concrete on the Coignet system. Engineers, Messrs. Carey and Latham, and contractors Messrs. Mowlem & Co.

Total cost 80,000*l.*, or 2*l.* 11*s.* 7*d.* per ft. sup. of new wharf accommodation obtained. About 82*l.* per ft. run, including approaches.

Docks.

Cardiff, Liverpool, and London wet docks, including wharves, gates, locks, machinery, etc.: 20,000*l.* to 35,000*l.* per acre of water area.

Aberdeen, Glasgow, and Portsmouth, dry or graving docks for repairs, including equipment: 2*l.* to 4*l.* per yard cube of internal capacity.

Steel floating docks for repairs, in terms of lifting power	10*l.* to 15*l.* per ton.
Dock gates of greenheart, 70 to 90 ft. wide and 40 to 50 ft. high, including hydraulic machinery	40*s.* to 50*s.* per ft. sup.
Ditto of steel, ditto, ditto	30*s.* to 40*s.* ,,
Caissons, traversing or floating, 60 to 90 ft. wide, and 30 to 40 ft. high, including hydraulic machinery	50*s.* to 100*s.* per ft. sup. of waterway.
Dock walls, of concrete, stone or granite, with concrete backing, including digging	25*s.* to 45*s.* per yd. cube.

Actual Costs of wet docks, including dock walls, gates, locks, machinery, etc.:—

	Per acre of Water Area. £
Avonmouth Docks, near Bristol (1868–77)	22,600
Barry Docks, near Cardiff (1889). Water area, 114 acres. Total cost, 3,072,000*l.*	26,947
Cardiff. Water area, 50 acres. Total cost, 1,500,000*l.*	30,000
,, Bute Dock Extension. Water area, 35 acres	22,000
,, West Bute Dock (1839). Water area, 22 acres. Total cost, 400,000*l.*	18,180
,, Roath Dock (1887). Water area, 33 acres. Total cost, 500,000*l.*	15,150
Glasgow, Queen's Dock	24,500
Hull, Alexandra Dock	28,900
Immingham, near Grimsby (1912). Water area, 56 acres. Total cost, including land, railway sidings, dock sheds, coal hoists, etc., 2,600,000*l.*	46,430
Liverpool, Alexandra Dock	23,300
,, North Extension. Water area, 83 acres. Total cost, 2,640,000*l.*	31,810
London, King George V Dock (opened 1921). Concrete walls 7 reinforced concrete jetties, entrance lock, &c. Water area, 64 acres. Total cost, with equipment, £4,130,000	64,531
London, St. Katherine's Docks	36,000
Newport, S. Alexandra Docks (1893). Water area, 20 acres. Total cost, 500,000*l.*	25,000
Swansea, Prince of Wales' Docks (1879). Water area, 28 acres	18,600

Actual Costs of dry or graving docks for repairs, including equipment :—

	Per yard cube of internal capacity. £ s. d
Aberdeen. Internal size, 524 ft. × 73 ft. at surface level. Total 46,000*l.*	1 15 0
Belfast (1905–12). Length over all, 901 ft. Total cost, 350,000*l.*	2 1 0
Glasgow. Internal capacity, 81,555 yds. cube. Stone and concrete	2 9 0
Hartlepool. Brick and concrete, 570 ft. × 75 ft. × 17 ft. deep	1 8 0
Liverpool. Gladstone Dock (1910–13). Total cost, 500,000*l.*	1 13 0
Otago, New Zealand. Internal capacity, 37,000 yds. cube. Total 75,000*l.*	2 0 0
Portsmouth. Granite with brick and concrete backing ; 42 ft. deep	2 0 0

See pp. 1523, 1528, 1537.)

DRAINAGE.

4-in. and 6-in. stoneware drains, jointed in cement, including trenches 3 ft. deep and concrete bed, 6 ins. thick	2*s.* to 3*s.* per ft. run.
Ditto ditto with manholes, ventilating pipes, etc.	5*s.* to 6*s.* per ft. run.
Manholes and inspection chambers, 3 ft. × 2 ft. 6 ins. × 3 ft. 6 ins. deep, complete, including digging, concrete, brick sides, iron cover, etc.	8*l.* to 10*l.* each.
Add extra for every additional foot in depth	16*s.* to 18*s.* per ft. deep.
Drains and sewers for estate development and town planning schemes	200*l.* to 400*l.* per acre.
Drainage and sewage disposal works for cities and towns	3*l.* to 6*l.* per inhabitant, 20*l.* to 30*l.* per house.

Reconstruction of Drainage, Stanhope Lines, Aldershot (1893).—Combined water carriage system with 4 in., 6 in., 9 in., and 12 in. glazed stoneware pipes (total, 54,670 yds. run), 2 to 6 ft. deep, 500 Jennings' latrines, 500 urinal stalls, 80 w.c.'s, with 3 gal. flushing cisterns, 200 gal. galvanised iron automatic cisterns, and 16 100-gal. brick automatic flushing tanks, with disposal of sewage by irrigation on War Department land. Occupation of barracks, 8,000 adults, 200 children, and 200 horses. Total cost, exclusive of sewage disposal works, 20,500*l.*, or 2*l.* 10*s.* per head of occupation exclusive of horses; 7*s.* 6*d.* per yd. run of excavation.

DRAINAGE OF LAND.

Agricultural, or subsoil, unglazed earthenware drain pipes laid dry in 12 in. or 15 in. lengths, without jointing material and ends simply abutting. Depths and distances apart vary according to nature of soil. Cost includes digging, filling, pipes, and laying.

	Cost per acre.
In compact or heavy soils, drains 5 to 8 yds. apart, and 2 ft. 6 ins. to 3 ft. deep	6*l.* to 10*l.*
In medium soils, drains 9 to 10 yds. apart, and 3 ft. to 3 ft. 6 ins. deep	5*l.* to 6*l.*
In porous or light soils, drains 11 to 22 yds. apart, and 3 ft. 6 ins. to 4 ft. 6 ins. deep	4*l.* to 5*l.*

DREDGING.

Dredging Plant.—Modern dredging appliances are of two main classes, with subdivisions and pre-war costs as follows :—

Class I.—Digging dredgers, comprising :

(*a*) Bucket dredger, or ladder (single or double), or elevator dredger, with a continuous band of buckets.

	£
With 5 ft. cube bucket, single ladder, raising 40 ft.	7,000
,, 15 ,, ,, ,, ,, 45 ,,	27,000
,, 27 ,, ,, ,, ,, 55 ,,	43,000

(*b*) Dipper dredger, with a single bucket at the extremity of a long arm or lever. Almost purely an American type.

With 1 to 2 yds. cube dipper, hull of timber, 1,600*l.* to 2,400*l.*
With 3½ to 4 yds. cube dipper, dredging to depth of 35 ft., 16,000*l.* to 18,000*l.*
With 10 yds. cube dipper, dredging to depth of 35 ft., 26,000*l.* to 28,000*l.*

(*c*) Grab or grapple dredger, with a drop bucket suspended at the end of a chain.
A twin-screw hopper dredger, with hopper capacity of 12,000 tons, fitted with five hydraulic grab cranes each of 5 tons bucket capacity, working to a depth of 47 ft., has cost 35,000*l.*

(*d*) Hand or bag and spoon dredger, which consists of a bag attached to a steel rim at the end of a long pole, and is suitable only for mud in ponds and canals.

Class II.—Suction or hydraulic dredgers, comprising:

(*a*) Sand pump dredger, with centrifugal pump.
A 2,000-ton suction hopper dredger would cost 50,000*l.*

(*b*) Suction cutter dredger, with water jets and rotary cutters.
A suction hopper dredger with hopper capacity of 70,000 cub. ft., capable of raising 4,000 tons of sand per hour from a depth of 70 ft., has cost 75,000*l.*

(*c*) Compound dredger, fitted with both the suction or suction cutter and a bucket ladder.
A sea-going hopper dredger, fitted with both ladder buckets (18 cub. ft.) and suction pumps, capable of dredging 400 to 650 yds. cube per hour from a depth of 50 ft., has cost 53,000*l.*
Rock cutters are not dredgers, but an auxiliary class.

Cost of Work.—Costs include use of plant, dredging, and removing and depositing excavated material at sea. Steam dredgers cost 10,000*l.* to 70,000*l.* each; steam hopper barges in attendance, of 800 tons or 800 yds. cube capacity, with a speed of 11 knots per hour, cost 18,000*l.* to 20,000*l.*; ordinary hopper and dredger barges, 300*l.* to 1,000*l.* Pre-war.

Description.	Material.	Per yd. cube.	Per ton.
Bucket dredging, or ladder dredging	Mud, sand, or soft clay Gravel or stiff clay	1*s.* to 2*s.* 2*s.* ,, 4*s.*	9*d.* to 1*s.* 1*s.* ,, 2*s.*
Grab dredging, or grapple dredging	Mud, sand, or soft clay Gravel or stiff clay	2*s.* ,, 4*s.* 3*s.* ,, 5*s.*	1*s.* ,, 2*s.* 2*s.* ,, 3*s.*
Hand dredging, or 'bag and spoon dredging'	Mud, sand, or soft clay Gravel or stiff clay	3*s.* ,, 4*s.* 4*s.* ,, 6*s.*	2*s.* ,, 3*s.* 3*s.* ,, 4*s.*
Pump dredging, 'suction or hydraulic dredging'	Mud, sand, or peat	6*d.* ,, 1*s.*	4*d.* ,, 9*d.*

Grab dredging can be done for as little as 2*d.* to 6*d.* per yd. cube, and sand pump dredging for 1*d.* ditto, but a great deal depends on the kind of spoil and distance to be carried.

Alluvial Mining.—Dredging for alluvial mining costs anything from 1*d.* to 1*s.* per yd. cube (pre-war), depending upon character of ground, depth, quantity treated, climate, transport, power, labour, management, types of dredges capacity of buckets, operating time, etc.

Mersey.—At the bar and in the entrance channels of the Mersey nearly fifteen million cubic yards of sand were removed annually at a pre-war cost of 6*d.* per yd. cube, exclusive of interest and depreciation on the plant.

Mississippi River (1907).—Three pipe-line suction-cutter dredges got up 1,279,000 cu. yds. including cost of idle time, for 4¼*d.* per yd. cube. In 1908 the same dredges lifted 989,000 cu. yds., ditto, for 5¼*d.* per yd. cube.

Newry.—After blasting the bottom in a depth of 6 to 8 ft. at low water, the material was removed by dredging at 4*s.* to 5*s.* per yd. cube.

New York Harbour (1909).—Four sea-going suction dredgers removed 10,786,638 cu. yds., including dredging, surveys, contingencies, and supervision, for 2*d.* per yd. cube. Another dredger disposed of 1,675,562 cu. yds. at 2½*d.* per yd. cube.

Panama Canal (1910).—Costs of removal of various quantities by different kinds of dredgers worked out at:

Removal of	6,083,902 cu. yds.	by	two sea-going suction dredgers	3¾*d.* per yd. cube
,,	1,372,665 ,,	,,	one ladder dredger	8*d.* ,,
,,	560,622 ,,	,,	,, ,,	1*s.* 1¾*d.* ,,
,,	1,013,485 ,,	,,	two small dipper dredgers	2*s.* 4*d.* ,,
,,	2,472,822 ,,	,,	two 20-in. pipe-line suction dredgers	1*s.* 2*d.* ,,
,,	5,800,000 ,,	,,	two dipper dredgers	2¼*d.* to 5¼*d.* ,,

Port Natal, Durban (1903–14).—Cost of pump dredging in sea, including all charges for working, maintenance, insurance, depreciation, and interest on capital, with coal at only 8*s.* per ton, 2¼*d.* to 7*d.* per ton of material handled.

Severn.—Blasting and dredging the marl beds, 4*s.* per yd. cube.

Siam (1920).—Dredging heavy clay from irrigation canal in Siam, 85 ft. wide by 8 ft. deep, by a Lobnitz dipper dredge with buckets of 2½ yds. cube capacity, working at a speed of 30 to 40 seconds per dip. Total quantity raised was 312,130 cu. yds. in one place, running 9 hours per day, or an average of 26,010 cu. yds. per month. Average cost for year was 3*d.* per yd. cube, including labour, oil fuel, supplies, repairs, and every expense except interest and depreciation. Repairs, 4·3 per cent. of total cost.

Tees.—Blasting and dredging. In 1875 holes were drilled in the bed of the river Tees 7 to 9 ft. deep and 10 ft. apart, from a dredger; then dynamite blasting in 2 lb. charges. Average depth of rock blasted 4 ft. 6 in., oolite shale. 110,000 yds. cube were blasted at 3*s.* 1*d.* per yd. cube, so as to be lifted by the dredger.

Ladder dredging in the Tees, mostly in hard boulder clay, and lifting stones and tree trunks, cost 1*s.* 6¾*d.* per yd. cube.

Thames.—Contract cost of lifting ballast and clay, by ladder or bucket dredgers from the Thames below London Bridge has varied from 1*s.* 4*d.* to 2*s.* 6*d.* per yd. cube, depending on distance material had to be conveyed.

(See also p. 1546.)

Rock-cutting and Dredging.

Rock-cutting Plant.—The sub-aqueous Lobnitz Patent Rock-breaker or Rock-cutter, made by Lobnitz & Co., Ltd., shipbuilders and engineers, Renfrew, Scotland, is usually employed. The rock-breaker chisel, or rock-cutter itself, consists of a compressed steel cone-shaped point fitted to a solid steel shaft, 15 to 18 in. diameter and 40 to 50 ft. long, depending on depth of water, and weighing from 6 to 25 tons. This drops 6 to 10 ft. on the same place, from a frame mounted on a barge fitted with steam winch, hoisting gear, steel wire ropes, mooring chains, etc. No explosives are used. The striking points are marked on a chart, and the holes are spaced about a yard apart. After a penetration of 3 ft. on one spot the rock is cut, and then dredged away in horizontal layers. The general result is 2 cu. ft. of rock broken per blow, suitable for bucket dredging afterwards to remove the pulverised stone. And 2 cu. ft. × 150 blows per hour on an average = 300 cu. ft. ÷ 27 = 11 yds. cube per hour for a single-cutter machine, or say 100 yds. cube per working day of 9 hours. Output of a double-cutter machine is about one-half more. A crew of four men is required on a barge with one cutter, and six men with two cutters, the barge being shifted after a hole has been made to the next position. Skilled labour is unnecessary. 1 ton of coal is consumed per working day by a single 10-ton cutter, and ½ tons by a double 10-ton cutter. The cost of oil, stores, and repairs does not exceed the outlay for coal and wages.

Blyth Harbour, Northumberland (1906).—Rock-cutting in friable to very hard sandstone by the Lobnitz Rock-breaker steel ram weighing 15 tons, falling 8 ft. to a depth of 3 ft. in the rock in 8 or 9 blows, to allow of being dredged to a depth of 2 ft. 6 ins. Average quantity was 908 cu. yds. of rock broken by one machine per week, night and day, allowing for all stoppages, and based on six months' working. Details per week for 908 cu. yds. was:

	£	*s.*	*d.*
Wages for men on dredger	16	1	6
Coal, stores, and water	6	10	7
Estimated cost of repairs, renewals of rams, ropes, etc.	22	0	0
Insurance at 30*s.* per cent. = 120*l.* per annum	1	19	2
908)	46	11	3
Rate per yard cube	0	1	0¼
Add 4 per cent. interest on cost of one Rock-breaker at 6,800*l.*, and 2½ per cent. for depreciation, making a further	0	0	2¼
Total cost per yard cube	0	1	2¼

As compared with blasting, the rock-cutting disintegrates and breaks the rock into smalle pieces, so that the quantity lifted by the dredgers in a given time is about 15 per cent. more tha that of blasted rock. The comparative cost of removal under the two systems of blasting an rock-cutting is as follows:—

	s.	*d.*
Blasting:—		
Drilling and blasting rock in position	3	0
Dredging and removing débris, 2*s.* 6*d.*+ 8*d.* for interest and depreciation on the dredger	3	2
Cost per yard cube	6	2
Rock-cutting:—		
Cutting rock by rock-breaker as already detailed	1	2½
Dredging and removing débris, 2*s.* 2*d.*+ 7*d.* for interest and depreciation on the dredger	2	9
Cost per yard cube	3	11½

Difference in cost per yard cube in favour of the removal of rock by means of the rock-breake was thus 6*s.* 2*d.* *less* 3*s.* 11½*d.*= 2*s.* 2½*d.* Saving on 500,000 cu. yds. executed was accordingl 55,200*l.*, after the drilling and blasting had been tried and abandoned.

Manchester (1905–6).—Deepening a length of 14 miles of the Manchester Ship Canal fro 26 ft. to 28 ft. by a Lobnitz Rock-cutter No. 1, designed to work in sandstone of varying degre of hardness, the average quantity broken per month (over a period of 10 months) being 6,4 cu. yds. at an average cost of 9*d.* per yd. cube.

The cost of rock-breaking and dredging on the same canal in April 1907, by the Lobnitz dredg was as below. The price of one Rock-cutter was 6,800*l.*, and if 4 per cent. is allowed for interes and 2½ per cent. for depreciation, the additional cost per yard cube is 2¼d., as added. 17,0 cu. yds. were broken, the rock being sandstone of different hardness, with some stiff marl.

	s.	*d.*
Breaking, excluding cost of plant, but including maintenance and repairs	0	5½
Dredging the broken rock	0	5½
Barging and tipping	0	6¾
Towage	0	2½
	1	8¼
Add interest and depreciation on cost of plant	0	2¼
Total cost per yard cube	1	10½

Suez Canal.—Deepened in 1884 by a Lobnitz dredger, with cutting rams of 3½ tons, ro removed in layers 20 in. thick, and the breaking up cost was 7*s.* 3½*d.* per yd. cube.

The canal was further deepened to 31 ft. in 1897 by a Lobnitz Rock-cutter with cutting ra of 13 tons, the average thickness of rock shattered was 31 in., and the average cost, includi repairs and depreciation, was 1*s.* 4*d.* per yd. cube. Cost of raising the rock by dredgers a carrying it away in addition.

ELECTRIC POWER STATIONS.

Town.	Total Cost.	Cost of Land and Buildings.	Kilowatts Housed.	Cost of Buildings per Kilowatt.	Total Cost per Kilowa
	£	£	No.	£	£
Brighton	717,738	149,431	5,400	28	133
Bristol	671,616	53,550	9,050	6	74
Chichester	20,000	{ 600 not land }	200	3	100
Glasgow	1,368,134	211,172	10,993	19	124
Hackney	280,982	42,394	3,372	13	83
Metropolitan	1,802,383	435,777	18,500	24	97

Tunbridge Wells	81,134	13,207	1,170	11	69

	£	£	
Electric light installations for cities and towns, with buildings, plant, and mains complete	80 to 130		per kilowatt.
	3 ,, 5		per c.p. lamp.
Steam plant power stations		24	per kilowatt.
Oil plant power stations	23 ,, 25		,,
Capital cost of generating stations		20	,,
Power and electric stations generally, brick, exclusive of plant and machinery. 10*l.* to 25*l.* per kilowatt			6*d.* to 8*d.* per f.c.
Aldershot electric lighting station (1902). Brick walls and slated roof			6½*d.* ,,
Curragh electric light generating station (1913–14). For three 100-h.p. Diesel oil engines, 66 kilowatts per engine, with a 750 ampere hour battery and accessory machinery. Contains a basement for engine beds, silencer chamber, and oil-fuel store, and above, on ground level, an engine-room, battery-room, store-room, two offices, and lavatory. Brick walls in cement mortar, 1 to 3, concrete foundations, engine beds and floors, steel sashes, steel roof, boarded and covered with asbestos slates. 99,700 feet cube. Building only, exclusive of plant and machinery. Total, 2,080*l.*			5*d.* ,,
Building, including plant and machinery. Total, 7,456*l.*			1*s.* 6*d.* ,,
Cost of foregoing per kilowatt housed, 10*l.* to 38*l.*			
Extension to Curragh electric light station (1920–21). For one additional 100-h.p. Diesel oil engine and plant, 66 kw., the extension of engine-room and exhaust pit being 12 ft. long, and same width and height as existing building. Construction also similar. A corrugated iron workshop, 18 ft. × 12 ft., is attached to the end of the brick extension, and included in total cost and cubing. Lump sum tender for both together. 17,600 ft. cube total. 17*l.* external services in addition. Building only, exclusive of plant and machinery. Total, 2,188*l.*			2*s.* 5¾*d.* ,,
Building, including plant and machinery. Total, 5,188*l.*			5*s.* 10¾*d.* ,,
Cost of foregoing per kilowatt housed, 33*l.* to 79*l.*			
East Ham electric power station, including tramway sheds and offices. Built by direct labour under the borough engineer. Total, 26,020*l.*			5½*d.* ,,
Salisbury engine-room and boiler-house (1904). Brick walls and slated roof, concrete floors			6½*d.* ,,
Usual charges for current for electric lighting			2*d.* to 3*d.* per unit.
Ditto for heating and power purposes			1*d.* to 2*d.* ,,

Engineering Factories.

Engineering factories, brick, exclusive of machinery		4*d.* to 7*d.* per f.c.
Material	52	per cent.
Labour	37	,,
Power	5	,,
Other costs	6	,,
	100	,,

Esplanades.

Marine Drive, Scarborough (1905).—Road 40 ft. wide, parade 20 ft. wide, and sea-wall 20 to 40 ft. high. Of concrete, on deep filling at base of cliff. Length, 1,400 yds. Total, 102,400*l.*, or 73*l.* per yd. run.

Excavating (Mechanical).

Methods.—Mechanical excavating greatly saves in labour, time, and cost over hand digging by pick and shovel, and may be classed under ten heads:

1. Steam shovels.
2. Trench-diggers.
3. Grab buckets.
4. Chain bucket excavators.
5. Drag-line excavators.
6. Scrapers.
7. Derricks and cranes.
8. Radial loaders.
9. Paving breakers.
10. Soil Transport.

1. *Steam Shovels.*—Steam shovel or steam navvy excavating for large masses of earth or rock in canals, docks, railway cuttings, etc., including filling wagons for removal. The buckets scoop

upwards with a general capacity of 1 to 3 cubic yards. Average output and pre-war costs o a 1½ cubic yard bucket steam excavator :—

	Yds. Cube
Ordinary soft soils	60–90 per hour, at 3*d.* to 4*d.* per yd. cube
Stiff clay or gravel	40–50 „ „ 4*d.* „ 6*d.* „
Strong ground or soft rock	30–40 „ „ 7*d.* „ 9*d.* „

Manchester Ship Canal (1887–94).—Forty-two million cubic yards of excavating in sand clay, gravel, etc., and 10 million cubic yards in sandstone rock. Average quantity for each steam navvy was 700 yds. per 10-hour day, or 70 yds. per hour, and cost 2d. per yd. cube, exclusive o cost of plant, depreciation, repairs, superintendence, etc.

Pre-war costs excavating and loading into wagons, 2*d.* to 6*d.* per yd. cube ; the harder th material the greater the saving. In easy soil as low as 1*d.* per yd. cube, including interest, depre ciation, and repairs, but this is exceptional ; in stiff clay 2*d.* or 3*d.* ditto. Costs per yard cube ar higher for small machines owing to the comparatively small output, and less for larger machine with big output.

Analysis of Costs.—Assuming a steam-driven crane navvy with 20 ft. jib centre and ¾ cu. yd bucket capacity is getting out clay at the rate of 30 yds. cube per hour, the costs (August 1922 would work out to approximately as follows, including excavating and dumping into clients wagons :

Output per day = 30 yds. cube per hour × 8 hrs. per day = 240 yds. cube.

	s.	*d.*
Working costs per day—		
One driver upon the machine	12	0
One boy as fireman	5	0
Two men assisting on ground at 8s. each	16	0
8 cwt. coal at 35s. per ton	14	0
Oil waste and stores	3	0
	50	0
240 yds. cube.		
Rate per yd. cube	0	2½

	s.	*d.*
Add capitalised cost, including depreciation at 10 per cent. per annum, interest 5 per cent. per annum, and maintenance 2½ per cent. per annum, making a further	0	1½
Total capitalised cost per yd. cube.	0	4

With an output of 80 yds. cube per hour for loose material the cost would be 2*d.* to 3*d.* per yd. cube

On bigger productions the cost per yard cube comes down owing to the working rates bein practically the same with the exception of a slight increase in coal consumption, so that on th larger machines the value would be well below the figure given. Fewer men are needed with electric power, or if caterpillar tracks are fitted.

Removing earth cover with a No. 6 ' Ruston ' crane navvy for the United Brick Co., Peter borough, came to 3¾*d.* per yd. cube. This previously cost 1s. 6d. per yd. cube by hand labour.

A 45-ton Wilson's steam-crane ' Jubilee ' excavator will work a clear 22-ft. face, and drive gullet 45 ft. wide, and can travel forward in 30 seconds as each advance is made.

Weight of Machine.	Capacity of Bucket.	Lift of Crane.	Depth of Cut.	Output per Hour based on 10-hour day.
tons.	cub. yd.	tons.	ft.	yds. cub.
17	¾	3	16	25–45
20	¾	4	16	30–50
25	1	5	18	40–70
30	1½	8	20	60–100
45	2½	15	22	100–140

Pre-war cost was 1*d.* to 6*d.* per yd. cube delivered into wagons.

The ' Erie ' revolving steam shovels are built in two sizes, and can be fitted with broa traction wheels, rail wheels, or caterpillar tread, and will climb 25 per cent. grades under thei own power.

Type ' A ' is used for stiff clay, gravel, or lighter shales, and Type ' B ' for stiffer clay, gravel, heavy rock shales, or blasted rock. The following rates of output are conservative and have often been exceeded. The yield depends upon plant management, and to keep the shovel busy ample hauling equipment is essential. To dig and load by pick and shovel costs seven times as much as the same amount with an ' Erie.'

Standard Type.	Capacity of Bucket.	Working Weight.	Approx. Price, August 1922.	Output per hour, ordinary conditions.
	cu. yd.	tons.		cu. yds.
A	½	13	£1,800	15–25 shallow cuts (10 in. to 24 in.) 30–40 deep cuts (3 ft. or over)
B	¾	19	£2,070	25–35 shallow cuts (10 in. to 24 in.) 50–60 deep cuts (3 ft. or over)

Two hundred to 300 yds. cube per day is good going in a trench cut, which may be 19 ft. deep. One ' Erie ' ditcher does as much as a 50-man gang in clearing sides and keeping cuts ditched.

Analysis of Costs.—The following approximate working costs per day (August 1922) are based on 200 working days per annum of digging and filling wagons or trucks with a Type 'A' ' Erie ' revolving shovel. The figures do not include any team or truck time.

	£	*s.*	*d.*
One driver or operator	0	15	0
One fireman	0	10	0
Two groundmen at 12*s.* 6*d.* each	1	5	0
Oil and fuel	1	0	0
Daily interest on capital invested, cost of machine £1,800 at 6 per cent.	0	10	10
Daily depreciation, say 10 per cent.	0	18	0
Total capitalised cost per working day	4	18	10

And £4 18*s.* 10*d.* per day ÷ 200 yds. cube output per day . . . 6*d.* per yd. cube.

(Output variable according to soil, shallow or deep cuts, wagon service, etc.) 300 " " " . . . 4*d.* "
400 " " " . . . 3*d.* "

For a Type ' B ' shovel the approximate working costs per day would similarly be :

	£	*s.*	*d.*
One driver or operator	0	15	0
One fireman	0	10	0
Two groundmen at 12*s.* 6*d.* each	1	5	0
Oil and fuel	1	1	0
Daily interest on capital invested, cost of machine £2,070, at 6 per cent.	0	12	6
Daily depreciation, say 10 per cent.	1	2	0
Total capitalised cost per working day	5	5	6

And £5 5*s.* 6*d.* per day ÷ 300 yds. cube output per day . . . 4½*d.* per yd. cube.

(Output variable according to soil, shallow or deep cuts, wagon service, etc.) 400 " " " . . . 3½*d.* "
500 " " " . . . 2½*d.* "
600 " " " . . . 2*d.* "

The ' B ' ' Erie ' with 4-men crew (driver, fireman, and two groundmen) is equal on deep cuts to 50 or more labourers, and on rock loading to 20 or 30 men. Assuming a labourer gets 3*s.* 3*d.* per hour, and can dig and throw into wagons ½-yd. cube per hour, this is equivalent to 3*s.* 6*d.* per yd. cube for hand labour. That is, 50 labourers × 4 or 5 yds. cube each per day = 200 to 250 yds. cube per day for the gang, whereas the Shovel will excavate 500 to 600 yds. cube per day and lift into wagons at a cost of about 2½*d.* per yd. cube.

Two loads of a ' B ' ' Erie ' dipper or bucket will completely fill an ordinary 1½ cub. yd. wagon and three ditto a 2 cub. yd. wagon.

Wagon Service.—There is no waiting with steam shovels, as the buckets or dippers lift ½ to 5 or even up to 6 cu. yds. in one bite, and the spoil is at once tipped into trucks or wagons an removed on rails with a minimum loss of time. One steam excavator requires at least one loco motive to look after it, with a speed not exceeding 8 to 10 miles per hour for sets of 30 to 40 wagon and stops of 15 to 20 minutes not more than 4 miles apart for 'fatting.' Allow ½ hr. at one end an ½ hr. at the other for running round the wagons, getting coal and water, and shunting out cripple ones. Steam-driven end-tipping wagons hold 2½ cu. yds. and side-tipping wagons 3 cu. yds measured in the solid. Maintaining them in good running order costs, pre-war, ½*d.* to 1*d.* p yd. cube per mile.

Generally, it takes 45 side wagons to keep a steam excavator going, if the haul is not mo than 1½ miles, and gradients are such that a 12- or 13-in. locomotive can handle 20 wagons in a s

Expenses of operating a locomotive depend on water (mostly), gradients, and coal. T pre-war labour cost of driving and repairing a locomotive is £1 per shift, including fitters and smith To this add foreman, boy turning points, general expenses 30 per cent., interest and depreciatio 1 ton of coal, repair accounts, water, oil, and stores, or £2 10*s.*, making a total cost per shift of £3 10 Washing and repairing engine while in shed adds 20 per cent. to wages paid for actual driving.

2. *Trench-diggers.*—The advantages compared with hand labour are economy, speed, ease control, and ready supervision. The cost is less than half that of hand labour, and the deep the trench the greater the saving. If a labourer can excavate and throw out by hand ½ yd. cu per hour in trench work it will take 120 men to yield a total output equal to one No. 36 machin which can dig 1 yd. cube per minute or 60 yds. cube per hour.

A 'Parsons' trench excavator, operated by petrol or steam, can dig a trench as detailed belo The prefix numbers indicate the maximum width in inches to which that particular machine w cut, and it will excavate any depth up to that mentioned.

Machine.	Working Weight.	Width of Trench.	Depth.	Rate per Minute.
	tons.	ins.	ft.	
No. 24	8	15, 18, 24	10	8 ins. to 10 ft.
No. 36	14	20 to 36	15	6 ins. to 10 ft.
No. 78	24	28 to 78	20	1½ ins. to 4 ft.

3. *Grab Buckets.*—Grab buckets are employed when it is impracticable to use a steam sho or trench-digger, and they can be operated by a special crane, or by attaching to an ordina steam crane or derrick. The common type is known as the clam-shell grab, which has jaws ope ing in and out. Capacity varies from ¼ to 3 cu. yds., and 20 to 30 cycles per hour of grabbin raising and swinging round, and discharging can be performed. The cost is about half that hand labour, and the saving is greater when under water. When dredging Limerick harbour wi a Priestman's grab the average pre-war cost of dredging and discharging was 1¾*d.* per ton.

4. *Chain Bucket Excavators.*—This excavator consists of a bucket ladder which scoops material and discharges it into wagons either above or below the engine. The machine is be for a definite profile, such as a railway cutting or reservoir, but the ground must be free of ro or boulders. A good size weighs 40 tons, and digs to 20 ft. deep or more at theoretically 1 cu. yds. per hour, but the actual output is about 66 per cent. of this rate.

5. *Drag-line Excavators.*—Generally speaking, drag-line and cable-line excavators are used f cuttings of large size for drainage purposes, for canals, handling sand and gravel, and in soi instances for preliminary road work over rough ground. These excavators can proceed in a direction, from railway station to works or from one job to another.

Bucket capacity 1 cu. yd., weight of machine 26 tons.
" 2 " " " 62 "
" 3 " " " 75 "

The cableway drag-line excavator has two masts, known as the head tower and tail tow with track cable between, along the line of which the bucket runs. Buckets, 1½ cu. yds. Wi an average haul of 225 ft. cost was 5*d.* per yd. cube, including maintenance, repairs, fuel, supe vision, and depreciation.

6. *Scrapers.*—Two types, 'drag scrapers' and 'wheel scrapers.' These are widely used in America for shallow excavation and grading work, and are drawn by one horse and one man, or by two horses and two men. The surface is first cut up with an ordinary plough, and the scraper then dragged over the ground to remove the loosened soil. Capacity of a drag scraper is about $\frac{1}{8}$ cu. yd.—wheel scraper much greater, about $\frac{1}{2}$ cu. yd.

7. *Derricks and Cranes.*—Contractors' locomotive or 'loco' steam cranes may weigh from 10 to 60 tons, and lift loads up to 25 tons, with a jib radius of 16 to 25 ft. The cranes have 'all motions,' *i.e.* lifting, lowering, revolving, jib adjusting, and travelling on rails with a gauge of 4 ft. $8\frac{1}{2}$ ins. to 12 ft.

Stationary or travelling steam cranes may be employed to work iron or flat-bottom wooden skips, which are like large buckets or open boxes respectively, and hold $\frac{1}{4}$, $\frac{1}{2}$, $\frac{3}{4}$, 1 cu. yd., or more, made to discharge from the crane over a wagon. Woodford's patent steel bucket skips are excellent, self-righting, and with safety catch.

8. *Radial Loaders.*—These are used for raising loose soil from the bottom of an excavation to the surface level, and have a chain of buckets attached to an inclined arm or boom, and a shoot, and are driven by an electric motor or a petrol engine. The usual capacity is 1 cu. yd. per minute, and the machine can load a 7-ton wagon in 7 mins. Cost of handling soil by this method is 1*d.* to 6*d.* per yd. cube.

The Haiss wagon-loader is a labour-saving device for dealing with loose materials, supplied by Millar's Machinery Co., Ltd., Pinners' Hall, London. It is a self-propelled petrol-driven machine fitted with a bucket elevator, operated by one man, and can load 5 cu. yds. into a truck in five minutes.

The saving in loading cost will enable a contractor to quickly regain the expenditure on these appliances.

9. *Paving Breakers.*—Breaking up old macadam, concrete, or paving was formerly done by steel wedges, sledge hammers, and crowbars by hand labour, but these are tedious and expensive compared with mechanical means.

Pneumatic paving-breakers show a cost saving of as much as 65 per cent., and a time saving of 75 per cent., over hand methods. These percussion tools are operated by compressed air from a portable compressor, driven either by petrol or electricity, which will work two to five large picks.

Weight.	Length overall.	Size of Steel.	Hose.	Air pressure.
lbs.	ins.	in. hex.	in.	
60	$24\frac{3}{4}$	$1\frac{1}{8}$	$\frac{3}{4}$	Over 80 lbs.
69	$26\frac{3}{4}$	$1\frac{1}{8}$	$\frac{3}{4}$	Under 80 lbs.

The steel cutters are of two kinds—one with a chisel edge, and the other with a moil point. An ordinary gang consists of three men—one compressor man and two breaker operatives. Each operative can break up an average of 245 yds. sup. of 9-in. concrete per day. Cost of running plant in oil and fuel is about 2*s.* per hour. Breaking up concrete surfaces, 8 to 20 ft. wide and 9 ins. to 12 ins. thick, in London streets, was 2*s.* 6*d.* per yd. cube, based on one portable compressor working four or five large picks.

One man with one paving breaker can smash up as much old tarmac on concrete roads for cutting trenches, etc., as nine men handling wedges and sledge hammers. Removing the top layer of a road came to 6*d.* per yd. sup. against 2*s.* per yd. sup. for burning and picking off.

10. *Soil Transport.*—It is impossible to maintain a big output with excavating equipment unless the surplus soil can be removed as quickly as the digging is done. Speed obviates the large number of trucks or wagons caused by slowness. Careful planning is required for rails, wagons, dumps, etc., and good organisation.

The types of transport may be classified as—

(*a*) Hand labour small receptacles, such as wheelbarrows or buggies.
(*b*) Horse-drawn vehicles, wagons or carts.
(*c*) Steam-driven wagons.
(*d*) Petrol-driven wagons.
(*e*) Narrow-gauge track with wagons.
(*f*) Standard-gauge track with trucks.
(*g*) Electrically driven trucks and vehicles.

(*a*) *Hand Labour.*—Net unit cost per ton-mile about 7*s.* 6*d.* (February 1922), for remova including loading up, wheeling, levelling, and return of empty, reckoning interest on initial outla depreciation, and maintenance.

Assume one man will do the equivalent to 10 ton-miles per week of 44 hrs. Output low an unit cost high, as many journeys are needed to transport a ton.

(*b*) *Horse-drawn Vehicles.*—1*s.* 6*d.* per ton-mile under ordinary average conditions, so this very economical compared with hand labour, or only one-fifth cost. It is also a flexible systen as horses and vehicles can be hired, but is not sufficient for extensive excavation schemes. Ti carts or tip-wagons are necessary, and the tipping can be done by a lever at the seat of the drive

(*c*) *Steam-driven Wagons.*—The haulage costs of these may be divided into standing charge which are constant, and running costs, which are governed by mileage. The costs per mi (July 1921) work out as below, including standing charges of insurance, rent, interest on fir cost, licence, registration, and wages; and running costs of fuel (coal, coke, or petrol), lubricant tyres, repairs, maintenance, depreciation on 'life,' etc., based on 200 miles per week, althoug 400 miles or more may be accomplished. The fuel-consumption basis, plus 20 per cent. f wastage, is 55*s.* per ton for coal or coke, and 2*s.* 8*d.* per gallon for petrol.

Unit.	4-ton Steam.	4-ton Petrol.	6-ton Steam.	6-ton Petrol.	10-ton Steam and Trailer Combination
Cost per ton-mile	4¾*d.*	6*d.*	3½*d.*	4¾*d.*	2½*d.*
Fuel mileage	20 miles per cwt.	7 miles per gal.	15 miles per cwt.	5 miles per gal.	13 miles per cwt.

Life of a steam wagon without trailer is taken as 12,000 miles.
,, petrol lorries is 25 per cent. less, say . 9,000 ,,
,, wagon tyres with trailer . . . 7,000 ,,
,, trailer tyres . . . . . 12,000 ,,

In calculating the depreciation allowance—

Life for a steam wagon without trailer is taken as 150,000 miles.
,, steam wagon with trailer . . . 120,000 ,,
,, petrol lorries . . . . . 100,000 ,,

The cost shows considerable saving over horse-drawn vehicles at 1*s.* 6*d.* per ton-mile. In fac the expense of transporting 4 tons 1 mile by steam wagon, 4¾*d.* × 4 = 1*s.* 7*d.*, is practical equal to that of 1 ton only the same distance by horse wagons.

The output of a 4-ton steam wagon with a speed of 8 to 10 miles per hour will run to 800 t miles per week, equivalent to 80 men by hand labour. To justify the initial outlay of an end- side-tipping wagon at £1,200 over a horse and cart, it should go 24,000 ton-miles to make t necessary saving, which is easy considering that its estimated life is 300,000 ton-miles of work be performed. With several steam wagons the gain is enormous, and the economy of employi them on large works amply justified.

(*d*) *Petrol-driven Wagons.*—A steam wagon is best for transporting a maximum tonnage o a maximum distance in a minimum time at a minimum cost; but for maximum mobility w lighter loads and for special suitability for intermittent work, the petrol vehicle has undisput claims, though its working costs are necessarily higher.

An investigation into the actual working records of 100 steam wagons by five different make and of 100 petrol vehicles by nine leading makers, showed that the average cost (1920) for hauli 5 tons per mile worked out at:—

For steam wagons, 1*s.* 5½*d.*, or 3½*d.* per ton-mile.
For petrol vehicles, 2*s.* 10½*d.*, or 7*d.* per ton-mile.

These rates included all overhead charges, 12½ per cent. depreciation, interest, fuel, wages, repa etc., over 15 million ton-miles. The annual saving of each steam wagon compared with pet was over £1,000. Steam wagons gave steadily consistent figures, whereas petrol lorries var widely.

Usual capacities of tipping petrol wagons are 1½, 2, 3, 4, and 5 tons, but 2 tons is the m useful. Cost per ton-mile, 6¾*d.*, based on 300 miles per week, including depreciation, interest capital, wages, tyres, renewals, fuel, etc.

(*e*) *Narrow-gauge Track with Wagons.*—Transporting surplus soil in side-tipping wagons on a narrow-gauge track is, under general conditions, more economical and far superior to ordinary manual labour with small receptacles or to horse-drawn carts. The track is commonly known as 'Jubilee,' industrial, or contractors' track, and the wagons as 'Jubilee' wagons. It is a portable railway with steel rails (10 to 20 lbs. per yd.) and corrugated steel sleepers, and the lay-out should be well planned. The tip wagons (½ to 7 cu. yds.) can be managed by hand labour, horses, or light locomotives.

Cost for hand-operated wagons on a level railway is 1*s.* 3*d.* per ton-mile.
„ horse-drawn „ „ „ 0*s.* 3*d.* „

Comparative costs for the different methods of transport:—

	s.	*d.*	
(*a*) Hand labour with wheelbarrow	7	6	per ton-mile
(*b*) Horse and cart	1	6	„
(*c*) Steam wagons, average	0	3½	„
(*d*) Petrol vehicles, average	0	7	„
(*e*) Hand-operated wagons on industrial track	1	3	„
(*f*) Horse-drawn „ „ „	0	3	„

Steam wagons are, therefore, cheapest for large quantities over considerable distances, and the industrial track (with horse labour) for small or large quantities over short distances.

(*f*) *Standard-gauge Track with Trucks.*—This system is restricted, as the first outlay is expensive, and the method is not so flexible as light railways. Large tipping wagons will be necessary, and no cost figures can be given, as the mode of transportation is for special circumstances.

(*g*) *Electrically-driven Trucks and Vehicles.*—These have not been extensively developed up to the present, but they are useful for short haulages and when continual stopping and restarting are unavoidable.

Taking a standard make of 5-ton electric vehicle, the 'fuel' cost at 2*d.* per unit works out at 2⅝*d.* per mile, with loads from 4 to 5 tons. Running costs, including interest at 6 per cent., depreciation at 10 per cent., tax, insurance, wages, charging current, rubber tyres, oil, grease, batteries at 5 years' life, etc.:—

Weekly mileage.	Load carried.	Annual Cost.	Running Cost.
	tons.	£	per ton-mile.
100	2	482	11½*d.*
100	3	482	7½*d.*
140	4	515	4½*d.*
140	6	515	3*d.*

Electrical traction on industrial or light railways, running costs 1½*d.* per mile.

Electric locomotives (costing about £450 per vehicle, complete with battery) will haul a load of 10 tons on a level track, and one charge of battery will give a normal run of 20 miles. One charge takes 14 units of electricity at 2*d.* per unit, which works out to 1½*d.* per mile run.

An electric locomotive can economically pull wagons on a narrow-gauge track in lieu of manual or animal labour, with great saving of time. The comparatively small capital will soon be recovered. The advantages are—reduced first cost, easy control, efficiency, flexibility, and low expenses of operation, upkeep, maintenance, and depreciation.

GAS WORKS.

Gasworks.—Gasworks complete, including buildings, plant, and distributing mains:

	Small Towns.	Large Towns. or Cities.
Per head of population	30*s.* to 40*s.*	40*s.* to 50*s.*
Per ton of coal carbonised per annum	5*l.* to 6*l.*	6*l.* to 7*l.*
Per million cubic feet of gas produced per annum	500*l.* to 600*l.*	600*l.* to 700*l.*

Land.—Area of land for the erection of works at least 2 acres per million cubic feet of gas per maximum diem.

Proportionate Capital Expenditure.—Including works, distribution plant, etc.:—

On buildings and works	38	per cent.
On district mains	55	„
On Parliamentary, promotion and engineer's expenses	7	„
	100	

Proportionate Cost of Parts.—Including buildings and plant :—

Retort house, including benches, fireclay retorts, etc.	25 per cent.
Purification buildings, with purifiers, gas scrubbers, etc.	30 ,,
Gasholders, iron or steel, with guide framing, brick-lined tanks, concrete bottoms, and excavation	40 ,,
Station meter-house, meter, and miscellaneous	5 ,,
	100

Retort-houses.—Including foundations and brickwork to benches, etc. :—

Exclusive of plant or machinery	5*d.* to 6*d.* per f.c.
Including retorts, ironwork, and fittings	1*s.* to 2*s.* ,,

Glover-West's system for vertical gas retorts, Belfast (1913) :—

70,950*l.* for a plant to carbonise 480 tons of coal per 24 hours,
=148*l.* ,, ,, ,, 1 ton ,, ,,

Gasholders.—Steel or iron telescopic holders, including guide framing, etc. :—

	Per 1,000 cub. ft. of capacity. £ £
Single-lift holders, up to about 50,000 cub. ft.	25 to 28
If of the spiral type, 25 per cent. less	20 ,, 22
Two-lift holders, about 250,000 cub. ft. capacity	16 ,, 20
If spirally guided, about 50 per cent. less	8 ,, 10
Large holders, from 2 to 3 million cub. ft. capacity	9 ,, 12
The 10½-million holder at Manchester cost	5
The 12-million holder at East Greenwich Works cost	5 guineas

(See pp. 2460, 2465.)

GROYNES.

There are four types of groyne construction in this country—timber, concrete bloc reinforced concrete, and chain cable. Cost of timber groynes for the seashore, comprisi creosoted fir piles with horizontal sheeting bolted thereto, and stiffened with ties and strut Piles well driven into sand or shingle, and executed as tide-work. Pre-war costs :

Light timber groynes, 1*l.* to 3*l.* per yard run.
Heavy ,, ,, 3*l.* ,, 6*l.* ,, ,,

The following particulars have been condensed from *Marine Works*, by E. Latham, M.I.C. (1922. 16*s.* Crosby Lockwood & Son, London), and the other books mentioned in each cas The first five examples are pre-war, and the last post-war.

	Cost per yd. ru £ *s.*
Bridlington.—Low timber case groynes, constructed of pitch pine piles, shod with 18-lb. pile-shoes, driven 8 ft. into the boulder clay in pairs, at 7 ft. 6 in. centres. 11 in. × 4 in. pitch pine planking inserted between the piles, so that a depth not exceeding two planks projects beyond the sand level. Timber all creosoted. Groynes spaced at a distance apart not exceeding their length, which was about 200 ft. First four groynes cost	2 14
Most of the others cost	1 16
For details see *Coast Erosion and Protection*, pp. 114–115, by E. R. Matthews, A.M.I.C.E. (1918. Charles Griffin & Co., London.)	
Eastbourne.—Timber groynes erected about 1886–96, some 70 yards apart, at right angles to the foreshore. Constructed of 9 in. × 9 in. pitch pine and oak piles, 6 to 16 ft. long, driven to an average depth of 9 ft., set 4 ft. 6 ins. apart, centre to centre, with walings 8 ins. × 6 ins. and 6 ins. × 6 ins. Planks, 9 ins. × 2 ins., are spiked to the piles in lengths of 20 ft. and over, to span four bays and break joint. Large oak land-ties fixed at right angles to the piles, and fastened to a smaller pile at back. The majority are high groynes, and were originally 8 to 10 ft. in height at shore end, and about 4 ft. at low end, and did not extend to low-water mark. The more recently constructed groynes vary from 4 ft. high at the land end to 2 ft. at low-water mark. Average length 100 yards, and cost 375*l.* each, or	3 15
Seven case groynes erected to the east of the pier in 1897. Pairs of 9 in. × 3 in. pitch pine piles, spaced 7 ft. 6 in. centres, with 9 in. × 3 in. planks inserted between. Average length 100 yards, and cost 68*l.* 15*s.* each, or	0 13
For details see *Coast Erosion and Protection*, pp. 104–106, by E. R. Matthews, A.M.I.C.E. (1918. Charles Griffin & Co., London.)	
Lowestoft (1901–1903).—North Denes. Four timber main groynes, three having a length of 290 ft., and the fourth 340 ft., spaced 1,500 ft. apart. Shoreward ends 4 ft. above high-water level, and seaward ends 3 ft. below the same level. For details see *Proceedings of the Institution of Civil Engineers*, vol. clxxxv. p. 106	22 1

	£	s.	d.
Southwold.—Timber groynes. For details see *The Protection of Sea Shores from Erosion*, p. 23, by A. E. Carey, M.I.C.E.	4	4	0
Withernsea (1873).—Six timber groynes consisting of 13 in. piles, 22 ft. long, 5 ft. apart, driven down 12 ft., with 11 in. × 4 in. planks, 13 in. × 6½ in. struts, and foot piles. Four are 300 ft. in length, and two 350 ft. Only three planks project above sand-level. For details see *Proceedings of the Institution of Civil Engineers*, vol. clix. p. 73	3	7	6
Blue Anchor (1921).—On the Bristol Channel, and in front of the Minehead to Watchet Road, north Somerset. Groyne 600 ft. long and two timber stockades, each 1,500 ft., parallel to existing sea-wall. Stockades consisted of 10 in. × 10 in. main piles of pitch pine, with 9 in. × 4 in. intermediate piles bolted to continuous walings. Half of total length of stockades had to be constructed by bedding the piles in mass concrete, necessitating trenching in rock. Engineer, E. Latham, M.I.C.E. Contractors, Messrs. John Cochrane & Sons, Westminster. Total about 30,000*l.* Cost per yd. run includes stockades	£25	0	0

Harbours.

Artificial harbours complete, including reclamation of land, dredging, enclosure walls, breakwaters, landing stages, lighting, buoys, cranes, etc.:

5,000*l.* to 10,000*l.* per water acre enclosed.

Colombo Harbour (1874–1914).—On the west coast of Ceylon and entirely artificial. It ranks twelfth among the greatest seaports, and there is ample space for 50 steamers besides smaller craft. The enclosed area is 650 acres (over a square mile), and depth 30 to 36 ft. at low water. Rise of tide at Ceylon is only 2 ft.

South-west breakwater, 1874–85, is 4,212 ft. long, built of concrete blocks weighing 18 to 30 tons on the sloping bond system, and cost 705,200*l.*, or 167*l.* per ft. run. Extension to ditto as a further protective arm, 1907–12, is 1,800 ft. long, also of concrete blocks, and cost 380,000*l.*, or 211*l.* per ft. run. North-east breakwater, 1894–7, is 1,100 ft. long, and constructed as a rubble embankment; the north-west or island breakwater, 1900–6, is 2,657 ft. long, and made of concrete; the two together cost 500,000*l.*, or 133*l.* per ft. run. Total length of the four breakwaters about 9,770 ft., with 5 lighthouses on them, and total cost 1,585,200*l.* Graving dock, 1900–4, is 700 ft. long, 85 ft. wide, and cost 400,000*l.*; patent slip, 1900–3, is 800 ft. long, and cost 43,000*l.*; coaling depot, on 24 acres of reclaimed land, has a frontage of 2,200 ft. with 18 jetties, and cost 163,000*l.* Other services, 821,900*l.* Total expenditure from 1874 to 1914 (forty years) was 3,013,100*l.* The small Fishery Harbour immediately to the northward has a rubble arm 800 ft. long, and cost 12,000*l.* The engineers were Sir John Coode, Son, and Mathews; and the resident engineers, Sir John Kyle, M.I.C.E., Mr. J. H. Bostock, M.I.C.E., Mr. John Kyle, M.I.C.E. (son of Sir John), and Mr. A. D. Prouse, M.I.C.E.

4,636*l.* per water acre enclosed; 162*l.* per ft. run, average of breakwaters.

Dover Harbour (1898–1909).—Original Admiralty Pier, 1,000 ft. long, was built in 1847–71. Dover Harbour Board then constructed a small commercial harbour of their own in 1890, between the existing Admiralty Pier and a new east pier, of 56 acres net area, afterwards increased to 75 acres by reclaiming the foreshore. The National Harbour was proceeded with in 1898–1909, and comprised the extension of the western breakwater, or old Admiralty Pier, from 1,000 to 3,000 ft., an eastern arm, 3,320 ft., and an isolated breakwater in the middle, 4,200 ft. Total sheltering works, 9,520 ft., or nearly 2 miles long, with two entrances 740 ft. and 650 ft. wide and 42 ft. deep at low water, enclosing 610 acres, exclusive of the 75 acres in the Commercial Harbour. Height of breakwaters from bottom of foundation to parapet top 60 to 120 ft. or an average of 90 ft., with 50 ft. average depth below low-water level, and 50 ft. average thickness, built of concrete blocks, weighing 10 to 40 tons each and faced with granite above low-water level. Works include a sea-wall, 3,850 ft. long, to protect base of cliffs, a lesser sea-wall, 700 ft., and reclaiming about 20 acres of land. Engineers, Sir John Coode, Son & Mathews. Contractors, Messrs. S. Pearson & Son, Ltd. National Harbour, 610 acres, cost 4,000,000*l.*, and inside Commercial Harbour, 75 acres, 1,250,000*l.*, or a total of 685 acres and 5,250,000*l.*

National Harbour:	6,557*l.* per water acre enclosed;	420*l.* per ft. run of breakwater.
Commercial Harbour:	16,666*l.* " " " ;	131*l.* " " "
The two combined:	7,664*l.* " " " ;	551*l.* " " "

(See also p. 1520.)

Heating.

The fewer the radiators, and the longer the run, the higher the cost per radiator. 15 ft. sup. of radiator should be supplied for every 1,000 cubic feet of space to be heated. Cost includes fittings complete, but is exclusive of boiler-house and buildings.

Heating buildings with boilers, pipes, and radiators	1*l.* to 4*l.* per 1,000 f.c.
Low-pressure hot-water heating	8*l.* " 10*l.* per radiator.
Hot-water work inside a building	1*s.* 6*d.* per ft. run.

(See also pp. 2488, 2499, 2500, 2501.)

Landing Slips.

Landing Slips, Milford Haven (1894).—Formed of Portland cement concrete, with shingl supplied by contractor, and 8 ft. wide × 3 ft. high, on 18-in. foundations. In tidework, and no exceeding 40 yards from shore. Excavation in boulders and shingle on beach. 30*s.* per foot run

Lighthouses.

Lighthouses. (All of Granite.)	Date.	Height of Focal Plane above High Water.	Engineer.	Total Cost.	Cubical Contents.	Cost per Ft. Cub. of Masonry.
		Ft.		£	f.c.	£ *s.* *d.*

Lighthouse, Northern Point, Northern Province, Ceylon (1914–16).—Tower is supported on reinforced concrete platform over hardwood piles, and built of dressed coral stone in lime mortar, cement rendered externally. Walls 2 ft. 7½ ins. thick above plinth, carried up with a uniform thickness at a batter of 1 in 48. Internal diameter of tower 8 ft. 3 ins., and height from top of foundation to reinforced concrete cap 91 ft. Fourth order light visible for 16 miles, and focal plane 97½ ft. above mean sea level. Cost, exclusive of lantern and ironwork above the cap 1,730*l.*, or 1*s.* 6*d.* per foot cube.

Lighting.—A complete gasworks plant for a lighthouse costs about 800*l.*
Annual expenditure for gas lighting, where works are installed . . . 72*l.* per light
" " " " where gas is supplied from elsewhere . 32*l.* "

A first-class electric lighthouse installation, including optical apparatus, lantern, dynamos, engines, air compressor, siren, etc., but not buildings, costs about 6,000*l.*

Maintenance.—Average annual cost of maintenance of an English shore lighthouse, with two keepers, is 280*l.*

Average annual cost of maintenance of an English shore lighthouse, with three keepers and a siren fog signal, is 450*l.*

Annual maintenance of a rock lighthouse, with four keepers and an explosive fog signal, is about 800*l.*; and of an electric light station, 1,100*l.*

Lightships.—Steel lightships, of average size, with power driven compressed air siren, cost about 16,000*l.*

Annual maintenance of ditto, including periodical overhaul, 1,320*l.*

Usual limits.—Length . . . . . 80 to 114 ft.
Beam . . . . . 20 " 24 "
Depth moulded . . . . . 13 " 16 "
Tonnage . . . . . 155 " 280 "

LIGHTING.

Buildings.—Cost of gas and electric lighting inside buildings, including service pipes, stop-cocks, ordinary brackets, pendants, switches, wiring, and other articles, fixed complete, but excluding meters, external gas mains, generators, etc.

	s.	*s.*	
Acetylene	20 to	40	per light.
Coal gas	30 „	50	„
Electric	25 „	50	„

Wiring, including all necessary wire, switches, fuses, lamps, holders, casings, etc., but not electroliers or shades, 15*s.* to 40*s.* per lamp.

Installing artificial lighting per 100 points, including oil-engine, dynamo, wires, lamps, etc. but excluding buildings:

Acetylene.	Petrol Gas.	Electric Light.
100*l.* to 200*l.*	150*l.* to 200*l.*	200*l.* to 300*l.*

Acetylene.—Cost of upkeep consists mainly in the purchase of carbide with occasional renewa of burners. A 25 c.p. burner of ordinary type consumes about 1 f.c. of gas per hour, which demands ½ lb. carbide. With calcium carbide at 15*s.* per cwt. the cost of such a burner works out at ½*d.* per hour. Total upkeep of a 100-light installation is between 20*l.* and 30*l.*, according to number of hours lights are used.

Gas Lighting of the Castle, Carlisle (1896).—Supply from City of Carlisle Gas Company's mains through a 600-light dry meter supplied by Company. 4 in., 3 in., and 2 in. cast-iron mains and 1½ in. to ¼ in. galvanised wrought-iron service pipes, underground pipes 3 to 3½ ft. deep. Fittings include 19 governors, 10 valves, 20 stopcocks, 10 dry meters, 572 burners, 10 Wenham lights, 12 Schulke lights, 20 Deimel lights, 18 Welsbach incandescent lights, 12 Sugg's lights, etc. Occupation of barracks, 731 adults and 72 married quarters.

Total, 1,144*l.* 36*s.* per light or point. 28*s.* per head.

Gas Lighting of Strensall Camp, near York.—Completed 1915, in extension of the York Gas Co.'s mains. Cost includes 3-in. external steel mains, 2 in. to ¼ in. wrought-iron branches, brick meter-house and meters, siphons, stopcocks, burners, excavation, fixing, etc., complete, in huts and 40 married quarters for about 1,260, total of officers, N.C.O.'s, and men. 376 incandescent burners and 584 flat-flame burners, or 960 lights altogether.

Total, 1,780*l.* 37*s.* per light or point. 28*s.* per head.

Electric Lighting, Army Pay Offices, York.—Feb. 1915. 84 electric lights, mostly of 100 c.p. each, including opal glass shades, wiring, cords, switches, fuses, etc., but not cable into building or any plant, as taken from the Corporation electric main in road. 18 officers and 300 clerks.

Total, 91*l.* 22*s.* per light or point. 6*s.* per head.

Electric Lighting, Army Pay Offices Extension, York.—Aug. 1916. One-storey corrugated iron building, lined with plaster slabs. 136 electric lights, mostly of 100 c.p. and 50 c.p. metal filament lamps, including pendants, opal and holophane glass shades, wiring, cords, 109 switches, fuses, distribution boards, etc. Direct-current supply on the three-wire system taken from the Corporation electric main in adjacent road. 24 officers and 400 clerks.

Total, 137*l.* 20*s.* per light or point. 6*s.* 6*d.* per head.

Railway Coaches.—

	£
Cost of fitting a railway coach with electric light	130
„ „ „ „ incandescent gas	34
Annual maintenance of an electric lit railway coach	13

STREET LIGHTING AT CROYDON.

(1910.)

Type of Lamp.	Number of Lamps.	Distance Apart.	Total Cost.	Average c.p. per Mile.	Cost per c.p. per Annum.
	No.	Yds.	£	c.p.	*d.*
Incandescent gas	2,137	80	7,062	839	15·86
Incandescent electric	90	66	288	1,373	13·71
Electric arcs	428	65	7,212	10,537	11·32

Locks.

Including foundations, invert, walls, gates, sills, machinery, lock-keeper's cottage, etc.

Brick and concrete	Per yd. cu. of internal capacity 30*s.* to 50*s.*
Stone and concrete	,, ,, 40*s.* ,, 60*s.*
Canal locks	each 5,000*l.* to 15,000*l.*
River locks	,, 15,000*l.* ,, 30,000*l.*

Marine Piers.

Timber and iron piers for seaside places, with creosoted fir or iron screw piles, averaging 40 ft long and driven up to 15 ft. in sand or shingle, including braces, ties, timber decking, railings tarring, gates, seats, etc.

Gangway or promenade portion	8*s.* to 12*s.* per ft. sup.
Landing stage or head to pier	10*s.* ,, 16*s.* ,,

Military Pier, Tilbury (1896).—450 ft. long by 16 ft. wide, or 7,200 ft. sup. Height above h.w.o.s.t. level, 4 ft., and above l.w.o.s.t. level, 20 ft. Foundation, 3 ft. of mud over 20 ft. of chalk, the distance bored. Substructure of wrought-iron piles, 10 ft. apart, with rod iron braces on which are fixed wrought-iron girders with intermediate joists supporting timber decking 18-in. gauge tramway rails, 24 lbs. per yard, and steam crane to lift 10 tons. Total cost, including 500*l.* for hoisting machinery, 3,200*l.*, or 8*s.* 11*d.* per ft. sup.

Batticaloa Jetty, Eastern Province, Ceylon (1900).—Timber pier, 50 ft. long, with return portion 22 ft. long, and 10 ft. wide. Cost, 5*s.* 6*d.* per ft. sup.

Galle Jetty, Southern Province, Ceylon (1916).—Jetty is 162 ft. long × 20 ft. wide, carried on concrete cylinders 6 ft. diameter, spaced 20 ft. centre to centre longitudinally and 14 ft. transversely, end pair being taken down to a depth of 20 ft. Special cylinders, 8 ft. diameter, form seats for two 3-ton cranes. Jetty is roofed for a length of 137 ft. Cost, 4,923*l.*, or 1*l.* 10*s.* per ft. sup. Cost of cylinders sunk, 6 ft. diameter, 3*l.* 19*s.*, and 8 ft. diameter, 5*l.* 3*s.*, per ft. run.

Kalkudah Jetty, Eastern Province, Ceylon (1901).—Jetty of iron, with wooden joists and planking, 165 ft. long × 28 ft. wide, and landings. Piles of H-iron section, 9 ins. × 7 ins. carried through a stratum of sand about 8 ft. into the coral bed of 1 to 2 ft. thick. Cross bracing, walings, fenders, etc. Corrugated iron roof over 122 ft. of length, supported on iron principals carried by H-iron standards, 8 ins. × 6 ins. Water 8 ft. deep at end of pier. Cost, including crane seat, 2,516*l.*, or 11*s.* per ft. sup. of platform area.

Paddiruppu Jetty, Eastern Province, Ceylon (1900).—70 ft. long with a tee head 30 ft. × 6 ft. wide, constructed of Palu timber with brick abutment. Cost, 8*s.* per ft. sup.

Mining.

(See pp. 2573, 2575, 2581, 2587, 2590, 2592, 2599, 2622, 2633, 2635, 2638, 2641.)

Pile Driving.

(See p. 610.)

Railways.

Average cost of railways, main lines, 4 ft. 8½ in. gauge, double track, total capital expenditure including land and all charges :—

	£	£	
In England	35,000	to 45,000	per mile.
,, Scotland	25,000	,, 35,000	,,
,, Ireland (5 ft. 3 in. gauge)	20,000	,, 25,000	,,
,, Europe	15,000	,, 25,000	,,

	£	£	
Main lines, construction work and stations only	10,000 to	20,000	per mile.
Light railways ,, ,, ,, ,,	1,000 ,,	3,000	,,
Permanent way, single line, light construction, 4 ft. 8½ in. gauge, in flat country, cuttings and banks averaging 3 ft., rails 55 lbs. per yard, ballast 15 ins. deep, including stations and permanent works, but excluding land and rolling stock	5,000 ,,	6,000	,,
Ditto, heavy construction, 75-lb. rails, and 24 ins. ballast	6,000 ,,	8,000	,,
Yearly maintenance of permanent way	200 ,,	250	,,
Rolling stock, single line, depends on kind of traffic	700 ,,	1,000	,,
Permanent way, double line, in excess of above figures	50 ,,	75	per cent.
Rolling stock ,, ,, ,, ,,	10 ,,	30	,,

Working expenses in England average 50 per cent. of the gross receipts.
,, ,, Scotland ,, 45 ,, ,, ,,
,, ,, Ireland ,, 40 ,, ,, ,,
Average gross receipts, 4*s.* to 6*s.* per train mile.

Railway Footbridges.—Of iron or steel, including foundations, supports, girders, floor, staircases, lattice sides, etc., erected complete, 5 ft. wide.
250*l.* to 350*l.* each, 30 to 40 ft. span, or 15*s.* to 20*s.* per ft. sup.

Railway Viaducts.—On the Great Western Railway there are a great many viaducts, especially in Cornwall, commencing at 50 to 60 ft. deep, and being as much as 90 or 100 ft., and even up to 150 ft., in the centre of the gorge. They are, as a rule, about 60 ft. spans between the piers, which is found to be the economical width. Segmental arches nearly, but not quite, semi-circular, 3 ft. thick at centre, and 3 ft. 9 ins. at the springing. Piers, 7 ft. 6 ins. wide at the top, tapering on every side at 1 in 32. This gives a pressure of about 8 tons per square foot on the masonry. The cost comes out for such a structure, carrying two lines of way, at 1*l.* per yard forward per foot high, measured from ground to rail. That is, for example, a viaduct 200 yards long, and averaging 70 ft. in depth, will cost 14,000*l.*

Avon Viaduct.—On the Midland Railway, and of brick. 720 ft. long, 51 ft. high, and 11 arches of 50 ft. span. Cost, 14,000*l.*, or 19*l.* per ft. run.

Congleton Viaduct.—On the Manchester and Birmingham Railway, and of stone. 3,080 ft. long, or over ½ mile, and 106 ft. high. Cost, 113,000*l.*, or 37*l.* per ft. run.

Dove Viaduct.—On the same line, and of brick. 1,716 ft. long, 88 ft. high, and 23 arches of 63 ft. span. Cost, 54,000*l.*, or 32*l.* per ft. run.

Viaduct over the River Eye, Berwickshire (1889).—Six openings of 50 ft. clear span, 55 ft. 3 ins. between centres of piers, and extreme height above bed of stream 60 ft. Total length of bridge 331 ft. and 15 ft. wide; single track. Abutments of 1 to 7 concrete. Five piers, 45 ft. high and 12 ft. wide at top, with 9-in. and 18-in. brick face and concrete hearting, and 9-in. brick wall up the centre. Superstructure of lattice main girders 8 ft. apart, with cross girders of 10-in. × 5-in. rolled iron joists, 40 lbs. per ft. run. Flooring of 4-in. planking, and the rails carried by longitudinal beams, 14 ins. × 12 ins. Cost, 3,700*l.*, or 11*l.* per ft. run, or 15*s.* per ft. sup.

Viaduct on the Gifford Light Railway, Haddingtonshire (1900).—Four spans of 42 ft. 8 ins., centre to centre of three piers, with 1 to 6 concrete foundations. Height to rail level above the bed of stream is 50 ft., and length over all 194 ft. by 18 ft. wide; single track. Masonry piers, haunches, and abutments, and brick arches over openings. Cost, 2,013*l.*, or 11*l.* per ft. run, or 12*s.* per ft. sup.

New York Elevated Railroad (1872–80).—Steam traction. Two lines of way supported on square wrought-iron lattice-work columns, let into cast-iron base blocks founded on brickwork and concrete, at distances of 37 to 44 ft. apart. Rails of Vignoles or flange pattern, of Bessemer steel, weighing 50 lbs. per yd. run, spiked to cross timber sleepers and guarded by longitudinal timbers. Sharpest curve is 90-ft. radius. Steepest gradient. 1 in 50 for a length of 800 yds. Stations about ½ mile apart, with platforms 200 ft. long and 13 ft. wide. No payment was made for way-leave along the streets, nor for compensation to frontages. Length, 35 miles. Total cost, 2,870,000*l.* Cost per mile of double track :—

	£
Foundations, columns, girders, superstructure, and permanent way	57,696
Railway stations and platforms	12,000
Rolling stock, 5 locomotives and 12 cars	11,680
Per mile of double track	81,376

Tube or Underground Railways.—Electric traction, as constructed in London. Two tracks, 4 ft. 8½ in. gauge, each laid in a separate tunnel, 11 to 12 ft. diameter. 300,000*l.* to 600,000*l.* per mile of double track.

	£	
London (Central), 1891–1900, 6 miles, 13 stations	580,000	per mile of double track.
London (Waterloo and City), opened 1898, 1½ miles	340,000	,, ,, ,,

Steam Traction.—Two tracks, 4 ft. 8½ in. gauge, laid in elliptical tunnel, 29 ft. wide and 17 ft. high, of 27 in. brickwork on concrete foundations.

	£	
London (Metropolitan), 1863–84	600,000	per mile of double track.
London (Metropolitan District), 1864–84	250,000	,, ,, ,,

Both the foregoing have since been converted to electric traction, completed in 1905. The Metropolitan has 32 electric miles, and the "District" 28 electric miles.

Cost of electrification only, exclusive of power stations, sub-stations, rolling stock, etc., 5,000*l.* to 10,000*l.* per mile of double track.

Cost of Indian Railways.—For the year 1895 the capital cost (rupee at 1*s.* 3¼*d.*) of Indian railways was :—

	£	
Standard gauge, 5 ft. 6 ins.	10,095	average cost per mile.
Metre gauge, 3 ft. 3⅜ ins.	4,519	,, ,,
Special gauges, 2 ft. 6 ins. and 2 ft.	2,093	,, ,,

London Railway Stations.

Particulars.	Cannon Street, London, South-Eastern Railway.		Charing Cross, London, South-Eastern Railway.	
	Total.	Per F.S.	Total.	Per F.S.
		£ *s.* *d.*		£ *s.* *d.*

Charing Cross Station roof has since been rebuilt with a different type (1906).

Light Railways.

Narrow-gauge Railways.—Approximate cost, including works and rolling stock, cuttings and embankments 2 ft. deep, and ballast 6 ins. to 14 ins. deep.

Gauge.	Weight of Engines exclusive of Tender.	Max. Load per Wheel.	Weight per Yard of each Rail.	Cost per Mile.
Ft. Ins.	Tons.	Tons.	Lbs.	£ £
2 0	6	1	20	1,500 to 2,000
2 6	9	1½	25	2,500 „ 3,000
3 0	12	2	30	3,000 „ 3,500
3 3½	17	3	40	3,500 „ 4,500
3 6	20	3½	50	4,000 „ 5,000

Belgium.—Over 1,000 miles of minor lines have been constructed at a cost, including rolling stock and all outlay, of rather less than 3,000*l.* a mile. These are generally on the metre gauge (3 ft. 3⅜ ins.), and as many of them appear to be laid on the roads the cost of land is very small. They earn about 6*l.* per mile per week, and working expenses are 66 per cent., or 4*l.* per mile per week. Net earnings of 2*l.* per mile per week give a return for over 3 per cent. per annum on the capital.

England.—In England a line on the standard gauge, with no heavy work, would cost twice as much as the Belgian metre gauge railways, or say 6,000*l.* per mile. As regards land, a light railway can seldom do with less than an average width of 1 chain (66 ft.) or 8 acres per mile, and this at 100*l.* per acre comes to 800*l.* per mile. Hence to run the line on a strip of green alongside a road would save a good deal of expense, but this might involve bad gradients and sharp curves and the maximum speed would be reduced. The following are some actual costs :—

Clogher Valley Railway, Ireland (1885–87).—Length 37 miles, 3 ft. gauge, 45-lb. rail, and runs for the most part on the side of the road. Cost, 3,300*l.* per mile. It earns about 4*l.* per mile per week, but this is mostly absorbed in working expenses.

Listowel and Ballybunion Railway, Ireland (1888).—Length 9 miles, mono-rail supported on steel trestles, fastened to steel sleepers resting on wooden sleepers, with gradients up to 1 in 45, and worked by locomotives. Cost, including rolling stock, 3,666*l.* per mile.

Wisbech and Upwell Light Railway, Cambridgeshire.—Length 5¾ miles, with 2 miles of sidings, standard gauge, 50-lb. rail, and runs mostly on the edge of the road. Cost, excluding sidings, 7,000*l.* per mile of line. The earnings are about 9*l.*, and the expenses 7*l.* per mile per week.

Agrails.—The Decauville tracks of the new light railways, or ' agrails ' as they are called, did admirable service at the front, both in France and Belgium. They can be laid at a cost of 2,500*l.* per mile, and are now being put forward as a rival or as an adjunct to motor lorry traffic, to save the costly wear and tear of roads and to relieve congestion. They can be run on the edge of existing roads, with sidings on the various farms, but are only suitable for comparatively flat districts. The old narrow-gauge railways were too solidly and expensively built, but the agrails are of very light construction and should prove most useful.

River Canalisation, see Section XXIX, p. 1575.

River Regulation, see Section XXIX, p. 1567.

Roads.

	£	£	
Main roads, 30 to 40 ft. wide, for heavy traffic, constructed complete, including bottoming, metalling, gravelling, watering, and steam rolling	3,000 to	5,000	per mile.
By-roads, 20 to 30 ft. wide, for light traffic, and ditto	ditto	ditto	1,000 „ 3,000 „

Cost per Head.—Cost per head of population for maintenance, repair, and improvements to roads, 6*s.* to 7*s.* per annum.

Damages.—Cost of maintenance has increased about 30 per cent. within recent years owing to traction engine and motor traffic. Damage through traction engines, steam lorries or carts is often assessed at 1*d.* to 2*d.* per ton per mile conveyed over the road. Damage by 'extraordinary traffic' sometimes 2*l.* to 3*l.* per mile.

Supervision.—Cost of supervision, including county surveyor's and clerk's salaries, office expenses, audit of urban accounts, etc., 3 to 6 per cent. on cost of maintenance.

(See also 'Roads,' Section XV, pp. 808, 844, 845, 849, 851, 855.)

Roofs.

Victoria Station and Charing Cross Station have since been entirely rebuilt.

Seaside Resorts.

Estimated costs, based on actual costs, 1927.

Bathing Pools, open, including accommodation for spectators, require a capital outlay of about 1*l.* per head of population, or 20*l.* to 30*l.* per square foot of water area.

Bathing châlets, with gas and water laid on, frequently fetch a rental of 35*l.* to 50*l.* a year.

Foreshore Lay-out is commonly 2*l.* per head of population, and in one case was 17*l.* per head.

Groyning, to form and maintain beaches, may cost 15,000*l.* per mile of beach.

Hard Tennis Courts, red or green, 6*s.* to 7*s.* per square yard of surface.

Sea-Walls.

Sea-walls to protect coast line, formed of 1 to 6 Portland cement concrete, 10 ft. high from base to top, 4 ft. average thickness, including foundations and excavating in clay, in tide-work, pre-war average cost—

6*l.* per yd. run, or 2*l.* per ft. run.

Pre-war actual costs from *Marine Works*, by E. Latham, M.I.C.E. (1922. 16*s.* Crosby Lockwood & Son, London.)

	Cost per yd. run. £ *s.* *d.*
Bridlington.—Alexandra sea-walls (1879). 340 yards long, of mass concrete 5 ft. thick at base and 3 ft. at top, curved on face. Concrete apron 9 ft. wide, and 2 to 2½ ft. thick, the toe-piece being 6 ft. deep and 18 ins. thick. Back of wall is battered 1½ in. per foot. Counterforts at 20 ft. centres. Wall is 20 ft. high, with projecting cornice, coping, and handrail. Chains embedded to act as bonds for the concrete. For details see *Coast Erosion and Protection*, pp. 49–50, by E. R. Matthews, A.M.I.C.E. (1918. Charles Griffin & Co., London); and *Proceedings of the Institution of Civil Engineers*, vol. clix. p. 65. Total, £5,657 .	16 12 9
Bridlington.—Beconsfield sea-wall (1888). 340 yards long, with Bramley Fall rock-faced stone and concrete backing. 1¾ in. wrought-iron tie-rods at intervals. 12 ft. 3 ins. thick at base, and 4 ft. at top, stepped and curved on face. Total height, 25 ft. 7 ins., with projectng cornice, coping, and handrail. Counterforts, 3 ft. 6 ins. by 3 ft. 6 ins, and 20 ft. apart, centre to centre. For details see *Coast Erosion and Protection*, pp. 47-48, by E. R. Matthews, A.M.I.C.E. (1918. Charles Griffin & Co., London.) Total, £10,000	29 8 3
Bridlington.—Sewerby sea-defence (1896). 305 yards long. Combination of rubble and timber, with two rows of 12 in. × 12 in. pitch-pine piles, 10 ft. apart. Front piles are 15 ft. long driven 9 ft. into the clay, and back piles 23 ft., driven 10 ft., with tie piece, 9 ins. × 4 ins. Face of 11 in. × 3 in. planking, and back planking 11 ins. × 4 ins., with 9 in. × 6 in. bearers and 11 in. × 4 in. ribs. Puddle clay backing, 2 ft. 6 ins. thick. Block chalk filling between the timber work. Foot-path on top. For details see *Coast Erosion and Protection*, pp. 86–88, by E. R. Matthews, A.M.I.C.E. (1918. Charles Griffin & Co., London); and *Proceedings of the Institution of Civil Engineers*, vol. clix. p. 65. Total, £3,000 . . .	9 16 8
Extension of ditto in 1899, by 82 yards, £788	9 12 2
Chatham (1913).—Reinforced concrete revetment on the De Muralt system on the banks of the Medway. Protects a length of 90 yds. of bank between two wharves	7 15 5
Frinton (1912–13).—Reinforced concrete apron 200 yds. long, to protect a stone pitched sea-wall at Frinton in Essex, which was being undermined by the waves. Apron 12 ft. wide, sloping 1 in 12, and 4 ins. thick, reinforced with Clinton fabric and ½ in. steel bars. Front toe wall, 9 ins. thick and 2 ft. high, with ½ in. steel bar reinforcement. 6 in. × 3 in. reinforced concrete ribs, with ½ in. steel bars .	2 5 0
Hornsea.—Reinforced concrete sea-wall. For details see *Proceedings of the Institution of Civil Engineers*, vol. cxxxv. p. 151	39 0 0
Lowestoft (1901–1903).—North Denes. Mass concrete sea-wall on steel piles, including steps, filling, and excavation. Total length with returns, 5,744 ft. run. Cost per yd. cube, 21*s.* 2*d.* For details see *Proceedings of the Institution of Civil Engineers*, vol. clxxxv. p. 106	5 11 6
Maintenance.—Maintenance of earthen embankments along river fronts or sea shores, about 18 ft. high to top of wall and protected by stone pitching or light reinforced concrete revetment; average cost of maintenance per annum (1910–13) when in normal repair	4*d.* to 4½*d.*

Sewage Works.

Sewage disposal works for cities and towns . . .	3*l.* to 6*l.* per inhabitant.
Bacteria filter-beds with earth embankments and floors, completed with clay puddle, and filled in with clinker or coke breeze 3 ft. deep	5*s.* to 10*s.* per yd. sup.
Ditto with concrete walls, and clinker or coke breeze 4 ft. deep	20*s.* to 30*s.* ,,

Precipitation and sludge tanks in the north-west of England, to treat a million gallons of sewage daily, built in 1910. From actual tenders received.

	£
Scheme with cast-iron tank plates	7,000
,, ,, brickwork in cement	6,000
,, ,, reinforced concrete	4,500

Bio-aëration System.—Complete works on the bio-aëration system, including aëration or circulating tanks, settling tanks of the Dortmund type, gauging chambers, sludge wells, motor houses, pump houses, etc., cost from 25,000*l.* to 30,000*l.* per million gallons, d.w.f., according to size and local circumstances (1924).

Activated Sludge Process.—The estimated cost for a complete activated sludge scheme, dealing with all storm water and treating all the sludge, is 1*l.* per head (1924).

Reading.—Activated sludge plant on the diffused air method, completed in 1924, designed to treat the whole flow of the city, amounting to 3½ million gallons d.w.f. per 24 hours, from an estimated future population of 120,000, cost 72,813*l.*, or 12*s.* 1½*d.* per head.

Strensall Camp Sewage Works, near York (1914–16).—For 1,000 nominal number of troops at 20 gals. per head per day, or 20,000 gals. sewage per day. Lift system, ground being low and sandy. Drainage connections comprised replacing 86 e.c.'s by w.c.'s, 18 additional w.c.'s, or 104 total w.c.'s, 234 gullies, and 80 manholes, with 4-in. and 6-in. stoneware drains gravitating to the ejectors. Brick engine shed, 15 ft. by 14 ft., for air compressor plant with 2 gas engines, and 4 ejector pits, with 12-in. concrete walls lined with ⅝-in. cast-iron plates, and concrete floors with expanded metal; pits octagonal in plan, 12 ft. internal diameter and 12 ft. average depth, containing 5 pneumatic ejectors, 25 gallons each, 1 pit holding 2 ejectors. 2½ in. steel compressed air mains from engine-house to ejectors, which raise sewage to the 5-in. and 6-in. cast-iron rising main drains and thence 1,700 yards (about a mile) to the outfall works. Total lift for sewage, 19 feet. Outfall works include two reinforced 6-in. concrete tanks, 20 ft. × 10 ft. × 6 ft. each, containing 7,500 gallons, or 15,000 gallons altogether; two brick sludge beds, 20 ft. × 10 ft. × 3 ft. each, with 10-in. screened ashes at bottom and 4-in. agricultural drains on 6-in. concrete floor; two circular filter beds, 46 ft. diameter, with rubble sides and reinforced concrete floors filled with 5-ft. furnace clinker, ½-in. to 4-in. gauge, the liquid sewage being distributed by a revolving sprinkler delivering 84,000 gallons per day. Special filter tiles on floor for aeration, concrete surface channel all round, and effluent then taken by waterways for land irrigation prior to discharging into existing ditch. Cost under five separate contracts:—

	£
Drainage connections, w.c.'s, stoneware drains, and manholes	2,710
Brick engine shed, and four concrete and iron ejector pits	775
Five ejectors, compressors, two gas engines, 2½-in. steel air mains, and 5-in. and 6-in. cast-iron main drains	1,837
Outfall works, including tool house, wire fence, and entrance road	2,035
Preparation of 13 acres of land, waterways and ditches for effluent	493
Total cost	7,850

Cost per head, 7*l.* 17*s.*, or 392*l.* 10*s.* per 1,000 gals. per day treated.

STANDS.

Permanent stands for athletic or race meetings, displays, processions, reviews, etc., constructed of brick, concrete, or reinforced concrete, with refreshment rooms, kitchens, offices, weighing and saddling rooms, lavatories, drainage, water supply, electric light, seats, etc., roofed or partly roofed—

2*l.* to 3*l.* per spectator, or head of accommodation.

Imperial Stadium, Wembley, near London (1920–1923).—Major axis, overall length, 900 ft. and maximum overall width 650 ft. Oblong of grass for football and sports in centre 492 ft. × 260 ft., with cinder running tracks, encircled by a wide stepped slope for spectators beyond which begins the structural work with terraces of concrete steps, roofed in for 650 ft. on each side of the stadium and provided with seats. Total accommodation, including seated grand stands, ring seats, standing enclosures and terraces, 125,200 spectators. A space of 16 ins. is allotted per ring seat, and 17½ ins. for a grand stand seat. Royal box, banqueting hall, 215 ft. × 70 ft., for 1,000 people, dressing-rooms, shower baths, lavatories, board-room, box office, gymnasium with seats for 250 spectators, recreation room with billiard tables and reading tables, buffets, cloak-rooms, tea-rooms for 600 people at a time, observation gallery, offices, press gallery, special heating, 96 turnstiles, telephones, electric lighting and cooking, wireless, good water supply and drainage, etc. The whole structure is of reinforced concrete on a steel skeleton, and there are 25,000 tons of concrete, 1,400 tons of structural steelwork, 31 terraces of concrete steps on steel joists, girders, and stanchions, and steel-framed roofs covered with corrugated asbestos sheets. Height from ground to roof eaves of stand is 50 ft. Two towers 160 ft. high, flank the royal entrance, and high walls on main frontage, with arched openings with an average span of 50 ft. The whole structure is larger than the Coliseum, Rome, which held 80,000 people. Architects, Sir John W. Simpson, F.R.I.B.A., and Mr. Maxwell Ayrton, F.R.I.B.A. Engineer, Sir Evan O. Williams, B.Sc., A.M.I.C.E. General contractors, Sir Robert McAlpine & Sons, and numerous sub-contractors. Total cost, 300,000*l.*, or 2*l.* 8*s.* per spectator.

TANKS.

Tanks, cast-iron, 5,000 to 10,000 gals., supplied only	1*s.* 6*d.* to 2*s.* per f.c., 3*d.* to 4*d.* per gal.
„ wrot.-iron „ „ „	2*s.* to 2*s.* 6*d.* „ 4*d.* „ 5*d.* „
Galvanised wrot.-iron square cisterns, 14 W.G., 50 to 500 gals. capacity, exclusive of fixing	2*s.* 6*d.* to 4*s.* „ 5*d.* „ 8*d.* „
Add if covered in at top	6*d.* to 1*s.* „ 1*d.* „ 2*d.* „

TELEPHONES.

Providing and fixing complete, including copper line weighing 150 lbs. per mile, with poles, brackets, insulators, etc.

25*l.* for ¼ mile ; 30*l.* for ½ mile ; 38*l.* for 1 mile ; and beyond, 30*l.* per mile.

TRAMWAYS.

Approximate Cost per Mile.	Single Track. £ £	Double Track. £ £
Electric tramways, overhead trolley system, with span wires, including buildings and equipment, but exclusive of generating station for electricity	9,000 to 12,000	15,000 to 20,000
Ditto, ditto, with side brackets or centre poles	7,000 „ 10,000	14,000 „ 18,000
Overhead equipment, including supports :—		
Span wire construction	1,200 „ 1,500	1,600 „ 2,000
Bracket arm construction	900 „ 1,200	1,300 „ 1,700
Permanent way, granite setts :—		
3 ft. 6 in. gauge, 100 lb. rails	4,000 „ 5,000	8,000 „ 9,000
4 ft. 8½ in. gauge, 100 lb. rails	5,000 „ 6,000	9,000 „ 10,000
Conduit system, centre slot, with underground wires, including special work	12,000 „ 15,000	23,000 „ 28,000
Cable tramways, mechanical, with underground cables, etc.	15 000 „ 20,000	25,000 „ 30,000
Horse tramways, with stables, cars, etc.	6,000 „ 9,000	12,000 „ 15,000
Steam tramways, with locomotives and cars	7,000 „ 10,000	13,000 „ 16,000

The cost of line per mile varies according to power station, plant, number of cars, cables, class of paving for permanent way, gauge and weight of tram-rails, etc.

PROPORTIONATE COST OF PARTS.

	Per cent.
Permanent-way construction	50
Overhead construction	10
Street alterations, etc.	5
Cables, feeder pillars, etc.	10
Power stations, buildings, plant, etc.	8
Tramcars	7
Supervision and incidental expenses	5
Compensation and legal charges	5
	100

Cars per mile of single line	3 to 6
Motor terminal voltage	500 to 550

Trolley vehicle system of electric railless traction :—	£ £
Capital cost per mile of route, double wire	2,000 to 3,000
Good overhead work, per mile	1,200 „ 1,500
Vehicles, cost of each	700 „ 800
Obtaining Parliamentary powers	1,000 „ 5,000
Cost of working per car mile	5*d.* „ 6*d.*
Traffic receipts per car mile	6*d.* „ 11*d.*

ACTUAL COSTS OF TRAMWAYS PER MILE.

Parts of Construction.	Edinburgh Cable Conduit.	South London (1903). Electric Conduit.	Electrical Overhead Trolley System. Glasgow.	Huddersfield.	Leeds.	Sunderland.

Aberdeen, overhead trolley system, 4 ft. 8½ in. gauge, exclusive of generating station, cost per mile of double track . . . . . £ 13,400

Darwen, overhead trolley system, 4 ft. gauge, exclusive of power station, total 35,000*l.*, per mile of double track 13,000

Dover, overhead trolley system, 3 ft. 6 in. gauge, exclusive of power station, total 28,000*l.*, per mile of single track 7,000

Manchester (1905), overhead trolley system, current provided by the lighting station, cost per mile of track 12,500
Permanent way, cables, and electrical equipment only, per mile of track . . . 6,575

Portsmouth, overhead trolley system, 4 ft. 7¾ in. 'Scotch' gauge, exclusive of power station, but including taking up old tram lines and concrete foundations and new ditto, cost per mile of double track 21,000
Ditto, including power station and machinery, ditto 23,900

Staffordshire, Bristol, and Coventry, capital expenditure on electric tramways per mile of single track, average 12,000

Wolverhampton, permanent way, electrical equipment, and cables, on the Lorain surface contact system, per mile 8,600

WORKING EXPENSES.	Per car mile. d.
Aberdeen, electric overhead trolley system, including interest on sinking fund	9·00
Birmingham, 1890–1, electric accumulator	9·90
" " cable traction	6·33
" " horse traction	9·79
" " steam traction	10·99
Dover, overhead trolley system, including interest on sinking fund	8·75
London County Council conduit tramways worked on purchased current, in 1905–6	8·02
Staffordshire, Bristol, and Coventry electric trams	6·30
Modern electric trolley lines generating their own current work	5*d.* to 6*d.*
" " " where current is purchased	6*d.* to 7½*d.*

The Peak Cable Tramway, Hong-Kong (1888).—Rises 1,207 ft. in a total length of 4,690 ft. Maximum gradient 1 in 2, and minimum 1 in 25. Three intermediate stations, and top and bottom termini. Single track 5 ft. gauge of two 30-lb. rails, and steel sleepers 24 lbs. per yard. Midway crossing place 130 ft. in the clear, above which the track is formed of three rails. Power-house at summit, with two engines, boilers, etc. Steel haulage cable, 3½ in. circumference, weighing 2 lbs. per ft. run. Rolling stock consists of two cars, each holding 45 passengers, and one ascends while the other descends, 9 minutes per trip. Total cost, 20,000*l.*, or at the rate of 22,516*l.* per mile.

(See p. 776.)

Tube Wells.

Driven tube wells sunk in ordinary ground, including use of tackle, well driver's time, and wrought-iron lap-welded tubes, approximate costs as detailed below; add pumps. The quantity of water obtainable depends on the water-bearing strata, and can be increased by connecting two or more wells together. See also 'Artesian Wells.'

Depth of Tubes, etc.

		Internal Diameter.		
		1¼ in.	2 in.	3 in.
Not exceeding 15 ft. deep	each	4*l.*	7*l.*	11*l.*
15 ft. to 20 ft. deep	,,	5*l.*	8*l.*	13*l.*
20 ft. ,, 25 ft. ,,	,,	6*l.*	10*l.*	16*l.*
25 ft. ,, 30 ft. ,,	,,	7*l.*	12*l.*	20*l.*
30 ft. ,, 35 ft. ,,	,,	8*l.*	13*l.*	22*l.*
35 ft. ,, 40 ft. ,,	,,	9*l.*	14*l.*	24*l.*
If beyond this depth, per foot deep		4*s.*	7*s.*	12*s.*
Sand strainers	each	20*s.*	30*s.*	40*s.*
Galvanised perforated driving points in 3 ft. lengths	,,	1*l.*	2*l.*	3*l.*
Special point of tough yellow metal for waters impregnated with iron	,,	2*l.*	3*l.*	5*l.*
Average quantity of water obtained, gallons per hour:		150 to 900;	300 to 1,500;	450 to 3,000.

Description of Pump.

	Size of barrel.		
	3 in.	3½ in.	4 in.
Standard pump, with valve door, supplied only, each	3*l.*	4*l.*	5*l.*

Tunnels.

Estimated Costs, 1924.

Cost of all tunnelling varies considerably according to locality, nature of excavations, pumping, size and depth of shaft, lining, distance to remove spoil, etc.

Adits.—Headings or tunnels at bottom of shafts, including excavating, removing, and raising material from a depth not exceeding 100 ft., and length of tunnel not exceeding 50 yds. from mouth of shaft, timbering, etc., complete, but exclusive of pumping:—

4 ft. × 6 ft. in clay, gravel, or soft chalk	per ft. run	2*l.* to 3*l.*
do. in hard rock requiring blasting	do.	4*l.* ,, 5*l.*

Aqueduct Tunnels.—As constructed in connection with large waterworks:—

Tunnels lined with concrete, 10 ft. diameter	per yard run	70*l.* to 100*l.*

Canal Tunnels.—As for inland navigation by ordinary canal boats, 72 ft. long × 7 ft. wide, average dimensions of tunnels being 16 ft. × 18 ft.:—

Excavation in clay, and lining with brickwork and concrete	per yd. run	50*l.* to 80*l.*
Excavation in rock, and lining with masonry and concrete	do.	80*l.* ,, 120*l.*

Irrigation Canal Tunnels.—As constructed in India to convey water from the mountainous districts to the lowlands, the average dimensions being 18 ft. wide by 12 ft. high. The longest is the Swat Canal Tunnel, 11,235 ft., and the next, the Pariyar Tunnel, 5,704 ft.

Irrigation canal tunnels in hard rock	per yd. cube	2*l.* to 3*l.*
,, ,, ,,	per yd. run	40*l.* ,, 60*l.*

Railway Tunnels.—Cost depends upon nature of excavations, lining required, etc. :—

For narrow-gauge or metre railways (3 ft. 3⅜ ins.), single track	per yd. run	50*l.* to	100*l.*
For standard-gauge railways (4 ft. 8½ ins.), single track	,,	80*l.* ,,	150*l.*
,, ,, ,, ,, double track	,,	150*l.* ,,	300*l.*

Ordinary Tunnels.—Ordinary tunnelling, cubic rate. It is generally cheaper to tunnel than to make a cutting over 50 ft. deep, but a good deal depends upon whether earth is required for embankments, and upon the kind of ground.

	Per yd. cube.
	s. *s.*
Tunnelling or driving headings, 20–50 ft. sup. sectional area, not exceeding 50 ft. below surface of ground or 50 yds. from shaft or adit, including use and waste of timbering, and drawing spoil to foot of shaft ready for removal :	
in ordinary ground, sand, or gravel	9 to 11
in stiff clay or shingle	12 ,, 14
in hard, solid chalk and flints	17 ,, 20
in soft rock not requiring blasting	45 ,, 50
in hard rock requiring blasting	55 ,, 60
Hoisting spoil from foot of shaft to ground surface, for any depth not exceeding 25 ft.	2 ,, 3
Extra only for every additional 25 ft. in height	1 ,, 2
Removing not exceeding ½ mile, and depositing	4 ,, 5
Excavating in large tunnels not less than 18 ft. wide × 20 ft. high, including fixing and removing temporary timbering and shoring, and removal of spoil not exceeding 1 mile :	
in ordinary ground, clay, or gravel	20 ,, 30
in soft rock not requiring blasting	30 ,, 40
in hard rock requiring blasting	40 ,, 70

Open Shield Tunnelling.—For subways or tunnels under rivers, with open headings and ordinary atmospheric conditions. Cost includes providing, fixing, and removal of timbering, shield, hydraulic jacks, pumping machinery, electric light, lifting excavated material to surface of ground, etc., but *exclusive* of concrete, masonry, or iron lining to tunnel ; for quantities not less than 3,000 yds. cube.

	Per yd. cube.
	s. *s.*
Open shield tunnelling, 100–200 ft. sup. sectional area, not exceeding 50 ft. below surface of ground nor 300 yds. from mouth of tunnel :	
in ordinary ground or sand	50 to 70
in stiff clay or gravel	60 ,, 80
Open shield tunnelling, 200–400 ft. sup. sectional area :	
in ordinary ground or sand	70 ,, 90
in stiff clay or gravel	80 ,, 100
Add for every additional 25 yds. in length	1 ,, 2

Pneumatic (or Closed Shield) Tunnelling.—For excavations in water-logged ground under air pressure, the closed shield having bulk-heads and air-locks, to admit and remove materials, workmen, etc. Cost includes providing, fixing, and removal of timbering, shield, hydraulic jacks, pumping machinery, air-compressing plant, electric light, raising excavated material to surface of ground, etc., but *exclusive* of concrete, masonry, or iron lining to tunnel ; for quantities not less than 3,000 yds. cube.

	Per yd. cube.
	s. *s.*
Pneumatic shield tunnelling, 100–200 ft. sup. sectional area, not exceeding 50 ft. below surface of water or ground nor 300 yds. from mouth of tunnel :	
in ordinary ground or sand	100 to 120
in stiff clay or gravel	110 ,, 130
Pneumatic shield tunnelling, 200–400 ft. sup. sectional area :	
in ordinary ground or sand	120 ,, 140
in stiff clay or gravel	130 ,, 150
Add for every additional 25 yds. in length	2 ,, 3

Tunnel Shields.—The cast-iron lining of a shield-driven tunnel is equivalent to about one-third total cost of tunnelling. The shield was first used by Brunel at the Rotherhithe tunnel in 1825, then by Mr. Greathead at the Tower subway in 1869, and the improved 'Greathead' shield in

1884 on the City and South London Railway. It consists of a steel ring with cutting edge, which is pushed forward by hydraulic jacks about 3 ft. apart. Tube railways and subways vary from 11 to 30ft. diameter, with 8–28 jacks per shield, and the tunnelling progresses at the rate of 30–60 ft. per week.

Costs complete with bolts, nuts, hydraulic jacks, etc., but *exclusive* of hydraulic machinery, piping, etc.:

Steel open tunnelling shields complete, 10–20 ft. external diameter, 40*l.*–50*l.* per ton
each 1,000*l.* to 4,000*l.*

Steel closed tunnelling shields complete, 12–25 ft. external diameter, 50*l.*–70*l.* per ton
each 4,000*l.* to 12,000*l.*

Tunnel Maintenance.—Cost of reinstating 3- to 6-ring double-track railway tunnels, in sand, clay, or chalk, including cutting out the inner ring and replacing by a brindle ring in cement, sometimes an additional ring, or part of the tunnel inverted, toe wall built to the footings, parts of the wall relined, or spaces behind walls and over arches filled with concrete, etc., the work being carried out day and night during traffic by contract or departmentally, a single line run at night, and taking various periods of from three to eight years to complete.

20*l.* to 40*l.* per lineal yard:

Other tunnels requiring more extensive repairs, such as shoring, bad portions cut out, and completely rebuilt, use of cement gun, etc.:

60*l.* to 500*l.* per lineal yard.

TUNNELS. Actual Costs.	Date. Years.	Length. Yds. Run.	Ft. Per Day.	Total in thousands	Per Y.R.
				£	£
Arlberg (6½ miles), Austria. 2 tracks in single tunnel, 25 ft. 3 ins. wide by 21 ft. high, partly lined with masonry	1880–84	11,210	28	1,204	107
Hoosac (4¼ miles), Massachusetts, U.S.A.	1855–76	8,390	7	2,014	240
Loetschberg (9 miles), Berenese Oberland	1906–11	15,973	36	2,556	160
Mont Cenis (7⅝ miles), France to Italy. 2 tracks in single tunnel, 26 ft. 3 ins. wide by 24 ft. 7 ins. high. Through solid granite, brick and stone lined	1857–71	13,712	9	2,880	210
Severn (4⅜ miles). 2 tracks in single tunnel, 26 ft. wide by 24½ ft. high, lined with 3 ft. brickwork. Water-logged ground and expensive pumping. Ventilated by fan 40 ft. diam. Hawkshaw, Hayter, and Richardson, engineers	1879–86	7,674	6	2,250	293
Simplon (12¼ miles), Switzerland to Italy. 2 single-track tunnels, each 16 ft. 5 ins. wide by 19 ft. 6 ins. high, 56 ft. apart axis to axis. Enlarged in 1911, at 1,600,000*l.* A. Brandt, engineer	1898–1906	21,578	28	3,120	145
St. Gothard (9½ miles), Switzerland to Italy. 2 tracks in single tunnel, 26 ft. 3 ins. wide by 24 ft. 7 ins. high, in granite and lined with masonry. Louis Favre, engineer	1872–82	16,426	18	2,300	140

WATER TOWERS.

Water towers, brick, exclusive of tanks and pipes, 1*s.* to 1*s.* 4*d.* per ft. cub., 2*s.* to 5*s.* per gal. Water supply inside a building, including service pipes, taps, etc. 2*l.* 10*s.* to 3*l.* per tap.

Beverley Water Tower, Yorkshire (1915).—Built of reinforced concrete on the Hennebique system. Two circular tanks, one within the other, the inner one holding 4,000 gals and the other

7,200 gals., or a total of 11,200 gals. Extreme diameter 34 ft., and 10 ft. internal depth, with three 6-in. cast-iron outlets, 4-in. sides, 2-in. curved dome top, 4-in. bottom, with beams under, supported on three 12-in. × 12-in. columns or legs, 30 ft. high, with 12-in. × 8-in. braces to latter and half-way up. Total height from ground level to top of tank, 42 ft. 6 ins. Concrete foundations, 2 ft. deep. Cost, including materials and erection, 312*l.*, or 27*l.* 17*s.* per 1,000 gals.

Bramham Moor Water Tower, near Tadcaster, Yorkshire (1916).—Designed by the Trussed Concrete Steel Co. Two united rectangular tanks, 4,000 gals. and 6,000 gals., or a total of 10,000 gals.; two iron ladders inside the tanks for cleaning purposes, and 3-in. cast-iron outlets; 5-in. sides, 3½-in. flat top, 6-in. bottom, with 24-in. × 10-inch beams under, supported on four 10 in. × 10-in. columns or legs, 20 ft. high, with 10-in. × 6-in. braces to latter and half-way up. Foundations 2 ft. 6 ins. deep in addition. Cost, including materials and erection, 298*l.*, or 29*l.* 16*s.* per 1,000 gals.

Curragh Water Tower (1900).—Heavily built, 34 ft. square externally and 94 ft. high above ground. 6 stories. Concrete foundations 6 ft. thick, brick walls in cement 45 ins. thick below to 22 ins. at top. Flat concrete roof, asphalted. Contains two cast-iron tanks, 20,000 gals. each, or 40,000 gals. total. Lower floors used as a fire engine station. Building only, 9,300*l.*; cast-iron tanks and pipes, 1,630*l.*; special fittings, 70*l.* Total, 11,000*l.*

1*s.* 4*d.* per ft. cu. 275*l.* per 1,000 gals.

WATERWORKS.

Waterworks, comprising reservoirs, filter beds, mains, valves, hydrants, etc., complete:

	£	
Birmingham	3	per head of population.
Dublin	2	" "
Edinburgh	3½	" "
Glasgow	3	" "
Liverpool	4	" "
Manchester	3	" "
Generally speaking	2*l.* to 4	" "
Small waterworks in Ireland (20 to 25 gals. per head.)	2*l.* to 2½	" "

Batticaloa Water Supply, Eastern Province, Ceylon (1915–16).—Supplies a population of 6,000 with about 20 gals. per head per day. One central well 10 ft. diameter, and two auxiliary wells same diameter, connected by adits 500 ft. long, yielding 180,000 gals. per day. From the central well the water is pumped through a 7-in. steel delivery main to the reservoir, 4 miles distant, from which the town is supplied by gravitation by 2-in. and 1½-in. distributing mains to 75 standpipes. 11½ miles of pumping and service mains altogether. Pumping machinery in duplicate. 3-in. centrifugal pumps, belt-driven by 18 B.H.P. oil engines, each pump capable of delivering 10,000 gals. per hour against a total head of 60 ft., or a total pumping capacity of 100,000 gals. per diem working 10 hours. Wells lined with 12-in. concrete, roofed with concrete slabs. Storage reservoir of 100,000 gals., with concrete walls faced in brick cement rendered and roofed with corrugated iron on steel trusses. Cost, 9,533*l.*, or 95*l.* per 1,000 gals., or 1*l.* 12*s.* per head of population supplied.

New Magdalen Barracks Water Supply, Oxford (1896).—Supply from City of Oxford Water Company's mains, constant service, Siemens' meter supplied by Company. • Davey's lift and force pump worked by steam power, and 6 in. cast-iron mains, 3 in. cast-iron domestic supply mains, and 1½ in., 1 in., ¾ in., and ½ in. galvanised wrought-iron service pipes, 3 to 4½ ft. deep. Reserve tank of 13,000 gals. for fire purposes, 60 ft. high on Armoury roof, 18 fire hydrants, 20 sluice valves, 40 stop valves, 280 bib valves, 50 3-gal. flushing cisterns to w.c.'s, and 6 200-gal. cisterns to latrines. Occupation of barracks, 500 adults, 100 children, and 5 horses. Total cost, including 800*l.* for machinery and erection, 3,500*l.*, or 5*l.* 16*s.* 8*d.* per head of occupation, exclusive of horses. 6*s.* 6*d.* per yd. run of excavation, exclusive of machinery, but inclusive of all fitments.

(See also p. 1480.)

IMPOUNDING RESERVOIRS.

Impounding reservoirs for gravitation waterworks to large towns, including excavations, embankments, etc.

200*l.* to 700*l.* per million gallons storage.

	£	
Arnfield, for Manchester waterworks	432	per million gals. storage.
Crowden " "	561	" "
Hollingworth " "	458	" "
Tellowfold " "	722	" "

Rooden, for Oldham	491	" "
Sheffield waterworks, structure only	210	" "
Ditto, including Parliamentary expenses, payments for compensation, etc.	485	" "
Swansea	550	" "
Swinshaw, for Ashton-under-Lyne and Stalybridge	405	" "
Walshaw Dean, for Halifax	469	" "

Curragh Old Waterworks Pumping Station.—Different dates, 1859, 1907, 1915, and 1921. Includes concrete reservoir, corrugated iron fence, brick engine house, boiler house, chimney shaft, workshop, coal yard, engineer's cottage, and new corrugated iron engine shed, engineer's hut, concrete tanks, old and new wells with bored Artesian tubes, 112 ft. and 276 ft. total depths respectively, barbed wire fencing, water-main connections, and 1,550*l.* worth of machinery, complete . . . . . 9,550*l.* total cost.

13½-in. Artesian bored tube well (1907), including boring 52 ft. deep sunk in sand and gravel from the bottom of existing dug well which is 8½ ft. diameter and 59 ft. deep . . . . . 3*l.* 5*s.* per ft. in depth.

Ditto including men's time, fixing plant, testing, and carriage, and hire of compressor . . . . . 7*l.* 10*s.* ditto.

(The cost of this Artesian well is included in the 9,550*l.* total.)

Curragh Old Waterworks Reservoir (1887–93). In connection with pumping station. Uncovered, with puddle clay embankments, stone-lined. Steel fence all round. Size, 320 ft. × 260 ft. × 6 ft. deep, and holds 3,100,000 gals. Total, 2,760*l.* 1½*d.* per foot cube. Reservoir now disused . . . . . 18*s.* per 1,000 gals.

Selby Waterworks Reservoir (1908). 800,000 gals. 12-in. concrete floor, brick walls, 50½ ins. thick at base and 22½ ins. at top, 6-in. concrete roof in arches of 7 ft. span. Total, 4,800*l.* . . . . . 6*l.* per 1,000 gals.

In the London Metropolitan area—

Cost of pumping averages 43 per cent. of the entire maintenance expenditure.
Cost of pumping alone averages 50*s.* per million gallons.
Repairs and renewals of water-mains and pipes, 34*s.* per million gallons.
Maintenance of water-mains or pipe-way, 24*l.* per mile.
Cost of filtration, 7*s.* 5*d.* per million gallons.

Assuan Dam (1898–1902 and 1907–12).—The Assuan or Aswan Dam was built for irrigation purposes at the head of the first cataract of the Nile, about 600 miles from Cairo and 350 miles above the Assiout barrage. It was formed across 5 channels of the river, which flowed at the rate of 16 miles an hour, and constructed of local granite masonry in Portland cement, on a similar rock foundation which had dykes of softer igneous material. The original dam was 1½ miles or 6,600 ft. long, 100 ft. thick at bottom, tapering to 24 ft. at top, with a maximum height of 130 ft. from base. Total weight of stonework over a million tons; 180 sluice openings, closed by steel gates; 1,000 Europeans and 20,000 natives were employed. The barrier affected the Nile for 140 miles higher up, and turned it into a regular lake. The greatest difference of level of water above and below the wall was 67 ft., and navigation was provided by a ladder of five locks, each 260 ft. long and 32 ft. wide. This first dam was completed in 1902, and held about 250,000 million gallons, which brought over a million acres of desert under cultivation. Engineer, Sir Wm. Willcocks, and contractors, Sir John Aird & Co. Cost was 2,500,000*l.* constructional work and 2,000,000*l.* for land and compensation charges, or 4,500,000*l.* altogether. This latter is equivalent to 18*l.* per million gallons of storage capacity, or 4*l.* 10*s.* per acre of irrigation area.

Between 1907 and 1912 the foregoing original dam was raised an additional 23 ft., thickened by 16 ft. on the downstream side, lock walls widened, and new dock gates provided, so that the impounding reservoir or lake was now 240 miles long, and the storage capacity increased by an extra 310,000 million gallons. Another million acres were also brought under cultivation. The greater depth submerged the Philae temples well up the river. Sir Benjamin Baker was consulting engineer. Cost of extension, including land and compensation charges, was 1,500,000*l.*, equivalent to 4*l.* 17*s.* per additional million gallons, or 1*l.* 10*s.* per additional acre.

Total present capacity as enlarged, 560,000 million gallons, bringing two million acres under total irrigation, at a total cost of 6,000,000*l.* This is equivalent to an average of 10*l.* 14*s.* per million gallons, or 3*l.* per acre of irrigation, as finally completed.

Burrinjuck Dam (1909-20).—Or Barren Jack. The highest dam in the Empire and in the Blue Mountains of New South Wales, at the confluence of three rivers—the Murrumbidgee, the Goodradigbee, and the Yass, which the dam ponds up 40 miles, 13 miles, and 19 miles respectively. The artificial lake so created has a surface area of 20 square miles, or 12,800 acres, and is 220 ft. greatest depth, giving a capacity of over 33,000,000,000 cubic ft., or about 206,250,000,000 gallons. The dam is a massive wall in a deep gorge with cliffs 1,000 ft. high and only 300 yds. apart, the sides being so steep that it was impossible to establish workshops upon them, and it was also across the bed of a river subject to floods. The granite masonry is 236 ft. high from rock to crest, set in cement, and 186 ft. thick at base, tapering to 18 ft. at top. The dam is of the arch type with convex side turned up stream; radius of curve 940 ft. and length of arc 900 ft. Flood-water tunnel 14 ft. × 13 ft., and two culverts cut through the cliffs at the ends of the dam itself. The water had to be conveyed 260 miles, and then distributed by miles of canals

Scraping Water Mains.

Various Towns.—Actual cost by pipe scraper driven by water pressure and supplied by Glenfield & Kennedy, Ltd., Kilmarnock:—

Year.	Place.	Diam. of Main.	Length of Main.	Total Cost.	Cost per Mile.	Cost per Yd. Run.	Obstructions removed, other than corrosion.	Gain in Delivery after Scraping.

over 1½ million acres of parched land, allowing the conservation of water for some 2,000 farms. Total cost about 3,000,000*l.*, or 14*l.* 11*s.* per million gallons of storage capacity, or 2*l.* per acre of irrigation area.

Croton Dam (1896–1911).—Or the Cornell Dam, which holds up the waters of the Croton River to form the great Croton lake reservoir which supplies New York with water, 33 miles away. A diversion canal, 1,000 ft. long and 2,000 ft. broad, was first excavated to divert the river before the dam itself could be commenced. The latter is about 1,200 ft. long, a maximum width of 216 ft., and greatest height 300 ft. from rock to crest, making it the highest in the world. It contains 833,000 cubic yards of masonry, and required 1,500,000 cubic yards of excavation. Owing to the rock being rotten, the foundations were carried in places 130 ft. below river-bed. Spillway built of granite blocks, some weighing 10 tons each. The lake behind the dam is 20 miles long, and contains 32,000,000,000 gallons of water. Three villages and numerous isolated buildings and farms were cleared away, and 75 miles of stone wall built round the reservoir. The outlay was excessive, as a large part was due to alterations and work which had to be afterwards undone, including the removal of the first core wall and taking up the earth on either side of it. Total cost about 1,600,000*l.*, or 50*l.* per million gallons of storage capacity.

Wentwood Reservoir, Newport (1894–1904).—Situated at Llanvaches, some ten miles from Newport, Monmouthshire. It has a water area of 41 acres, a depth of 86 ft., and a capacity of 410,000,000 gallons. The great dam, which is 456 ft. above sea level, is 97 ft. high, 800 ft. long, and 700 ft. wide at base, gradually tapering to 30 ft. wide at top. The inside slope is pitched from top to bottom. The valve tower and outlet are placed quite independently of the dam at the eastern end, and the culvert, which runs for a length of 900 ft. through the dam, is 6 ft. diameter and carries two water mains. Water is drawn into the reservoir from two streams in the Newchurch valley by means of a tunnel, which ranges from 3 ft. diameter at the Newchurch end to 6 ft. at the reservoir end; length of tunnel, 3,683 yds. Total cost, about 390,000*l.*, or 951*l.* 4*s.* per million gallons of storage capacity.

Scraping Water Mains.

Ayr.—Scraping 14-in. and 16-in. cast-iron water mains, 14½ miles long, at Ayr, between Loch Findas and the service reservoir at Dalrymple, in 1915. Pipes laid 28 years before, but incrustation reduced capacity by 30 per cent. Scraper weighed 3 cwts., and was driven by a pressure of 15 ft. head of water. When this pressure was unobtainable the instrument was pulled through by a chain. Pipes were divided into sections with inspection boxes, and each section was done twice, the scraper travelling at the rate of 2 miles an hour. Capacity of mains was at once increased by 37 per cent.

For 14-in. pipes the scraping alone cost 13*l.* 8*s.* per mile, or 2*d.* per yd. run.
„ 16-in. „ „ „ 12*l.* „ „ 1⅞*d.* „
„ 14-in. pipes the total cost was 34*l.* 5*s.* „ „ 4¾*d.* „
„ 16-in. „ „ „ 46*l.* 10*s.* „ „ 6¼*d.* „

Scraping is necessary every 3 years, owing to rapid reincrustation.

Prestwick.—Scraping 6 in., 8 in., and 10 in. water mains leading from the filters to the town, in 1923. In all 7,100 lin. yds. of pipes were scraped, and over 8 tons of corrosion removed. The pressure heads after scraping, as taken at air valves along the mains, showed an increase overall of 20 ft. The cost worked out at 1*s.* 5*d.* per yd. run.

Cleaning.—Cleaning 4 in. water main by the patent Powrcleer apparatus, supplied by the British Pipe Cleaning Co., W. & J. Glossop, Hipperholme, Halifax, for a minimum quantity of 1,000 yds., 1*s.* 4*d.* per yd. run (August 1922).

SECTION XLVI

DEPRECIATION OF PLANT AND MACHINERY—INCOME-TAX ALLOWANCES

(Contributed by Alfred B. Searle, Licensed Appraiser and Valuer.)

SECTION XLVI

DEPRECIATION OF PLANT AND MACHINERY—INCOME-TAX ALLOWANCES.

(Contributed by Alfred B. Searle, Licensed Appraiser and Valuer.)

Depreciation is a term applied to the reduction in value which occurs in plant or machinery, no matter whether they are in use or stored. The amount of depreciation is affected by the condition in which they are kept and by the availability or otherwise of more suitable appliances.

The loss in value is most properly met by an annual charge (to which the term 'depreciation' is commonly applied); the total of such charges should, when the appliance is worn out, discarded, or replaced by another, be equal to the difference between the original cost and the sum obtained (if any) by the sale of the worn-out or discarded appliance. Thus if a machine costing 1,000*l.* is discarded as useless after ten years and then is sold for only 10*l.* the total depreciation is 990*l.*, the annual depreciation is 99*l.*, and the residual value is 10*l.* The depreciation may be affected by any sums spent on renewing parts of a machine or plant, though these are usually charged separately in the accounts, as *renewals*.

The following terms are important:

Deterioration is the loss in value due to the lapse of time and to the use of the appliance. It occurs more rapidly when a machine is used than when it is stored under good conditions, but may be just as serious if a machine is stored under unsuitable conditions. In deterioration is also included the loss in value which occurs directly the ownership of anything has been transferred from the seller to the buyer, the 'second-hand value' being always less than the market price when new; the difference forms part of the loss by deterioration.

Obsolescence is the loss in value which occurs when a more suitable appliance can be used for the same purpose. It occurs when a machine is discarded, long before it is worn out, because another machine is more profitable to use.

Renewals are the cost of replacing worn-out or damaged portions of machinery or plant. To some extent they reduce the depreciation, but for convenience are usually treated quite separately. The Inland Revenue officials, for some purposes, take renewals instead of depreciation when calculating allowances for income-tax assessments. Thus, instead of allowing 3*l.* per annum as the depreciation on a typewriter, they allow nothing until the typewriter is replaced by another one; then they allow the cost of the new machine less the sum obtained by the sale of the old one, or a sum estimated to be obtainable for it.

Residual Value is the value of a machine or plant at the end of a given period—usually, but not necessarily, when it is worn out or discarded. In dealing with the estimated life of plant or machinery, the residual value of such plant or machinery when its period of usefulness has expired must be taken into account, and with plant of special nature it may generally be assumed that in proportion to its special character its residual value will be low. Plant of general character, engines, boilers, shaftings, pulleys, etc., carries a high residual value in the event of displacement.

Diminishing Value is the reduction in the value of plant or machinery as the result of depreciation or obsolescence, or both. The term is also used to indicate the value obtained by deducting depreciation for one year at a given rate, and then applying the same rate to the reduced value so obtained. Thus, if a machine costing 1,000*l.* is depreciated at 10 per cent. per annum on the diminishing value it will be worth 900*l.* at the end of the first year, 900*l.* — 90*l.* or 810*l.* at the end of the second year, 810*l.* — 81*l.* or 729*l.* at the end of the third year, and so on. This method is largely used because of its convenience, but it requires a larger rate of depreciation than when the rate is calculated throughout on the original value. In recent years there has been a tendency to revert to the basis of original cost. For instance, a rate of 10 per cent. on the original cost will exhaust the value in ten annual instalments; but a rate of about 16½ per cent. would be required to exhaust the value in the ten years if calculated on the diminishing value remaining after the deduction of depreciation in each year.

The argument in favour of basing the calculation on the diminishing value is that the sums written off in the earlier years were greater when the repairs were small, and this tended to equalise matters. Too often, however, the two factors of rate and basis have not been settled together, and consequently the basis of diminishing value has had the effect of leaving a considerable value in the books when the plant has disappeared. For instance, a 5 per cent. rate generally carries the impression of a twenty years' life, yet taking 100*l.* as the cost, and writing off on the diminishing value, the balance left at the end of the twentieth year is 37*l.* 14*s.* After twenty-one years' service the residual value of the plant would be, roughly, one-third of the first cost, a figure far too high in most cases. Besides, by adopting the basis of original cost, the position is much clearer for any revision of the rate at any subsequent period.

Rate of Depreciation.—This is usually expressed as a percentage of the original value of the plant or machinery, or on what is known as the diminishing value. The rate of depreciation is based on the assumed durability of the appliance, on its residual value, and on whatever allowance should be made for its becoming obsolescent before it is worn out. The determination of the rate of depreciation of various kinds of machines, etc., requires special skill and experience, and has given rise to specially trained appraisers or valuers, each of whom has expert knowledge of certain classes of plant or machinery; a valuer who is an expert on brewing appliances would probably know little of cotton-spinning, bricks, or presses, and *vice versâ*. It is, therefore, important that valuations should be made by men of *special* knowledge and not (as is usually the case in valuations for rating assessments and some other purposes) by men with only a general knowledge.

As different parts of a plant and different machines wear out or become obsolescent at different speeds, it is desirable to decide on a rate for each separate machine or appliance, though some grouping is desirable.

There is much difference of opinion as to what are suitable rates of depreciation, especially when accurate data on which to base them are not available. The following figures are only approximate, but they give a useful *general* idea, which may be greatly modified in particular cases.

Motive Power, Boilers, Engines, etc.—Some authorities place the depreciation on engines as high as 12½ per cent., and boilers at 10 to 15 per cent. Much depends on stress of working and the water. Mathieson places the life of a boiler at fifteen years, with renewal of the furnace at the end of ten years, and recommends a rate of 7½ per cent. per annum on the diminishing value on this class, no provision being made for obsolescence. This is, however, an extreme view.

Power Transmitters.—Shafting, pulleys, and plant under this head have, as a rule, a high residual value, even if displaced, and a rate of 5 per cent. will usually be found sufficient. Belting should be classified as loose tools. In this class a rate of 10 per cent. would be desirable. No provision is made for obsolescence.

Process Plant, Fixed.—Under this head would be placed all heavy process plant, the renewal portions of which are classified under their separate heading. The deterioration would then be met by a rate of 2½ per cent., the renewal rate at 2½ per cent. An obsolescence rate depending on the nature of the processes will also be needed; it may be 6 per cent.

Process Plant (Wearable).—For this it is necessary to provide a heavy renewal rate. By the dissection of this plant the separation of the different details can be secured, and it is easy to apply to each a distinctive rate for renewals applicable to its character and requirements, based on experience. It will usually be at least 10 per cent.

Process Plant (Loose).—In the case of loose tools, the yearly valuation gives the most reliable results. In some cases there is an annual increase in this class, but this should verify itself. It is to be remembered that at a going-concern valuation this cannot, in the nature of the plant, work out at more than half the original cost value.

Accessory Plant.—Usually has a high residual value due to general utility, and consequently a rate for deterioration of 2½ per cent. and a renewal rate of 5 per cent. should suffice.

Horses, Carts, Harness, etc.—The risks and depreciation on this class are too great to include in any average rate. A revaluation annually gives probably the best results.

The following rates of depreciation have been authorised by the Government of Australia in connection with the Federal income-tax on industrial establishments:—Boilers, 5 per cent.; boring machinery, 10 per cent.; cables, aerial, 7·5 per cent.; cables, underground, 2·5 per cent.; condensers, 5 per cent.; cranes, 5 per cent.; elevators, electric, 7·5 per cent.; elevators, hydraulic 10 per cent.; engines, steam, 5 per cent.; foundry cupolas, 15 per cent.; furniture, 5 per cent.; generators, 5 per cent.; machine tools, 5 per cent.; machinery used in ordinary manufacturing, 5 per cent.; meters, switchboard, 7·5 per cent.; motor trucks, 10 per cent.; patterns, 15 per cent.; pumps, 5 per cent.; galvanised iron tanks for rain water, 5 per cent.; galvanised iron tanks for other water, 10 per cent. The figures are based on the *diminishing value* of the assets and not on their original cost.

The following table, by Preece, gives (*A*) the approximate life in years of the various classes of machinery, etc., in an electrical undertaking if properly maintained, and (*B*) the probable residual

value at the end of that term in per cent. of original cost. It affords a useful means of checking any suggested rate of depreciation on the appliances, etc., mentioned, but is very incomplete and tends to include figures in column A which are too large for present-day conditions.

	A.	B.		A.	B.
Foundations	100	nil	Cables (solid in wood trough)	40	12
Buildings	80	nil	Buildings (sub-station)	50	nil
Boilers (water tube)	25	5	Sub-station equipment	25	12
Boilers (Lancashire)	22	3	Accumulators	15	10
Dynamos and alternators	30	8	Arc lamp-posts	40	5
Engines and other machinery	25	6	Arc lamps	12	5
Cables (armoured)	35	15	Electric motors	25	9

Methods of Estimating Depreciation.

Appraisers and valuers have various methods of estimating the depreciation of plant and machinery, and two men of equal skill may not agree in their estimate because they use a different method, or because they have different ideas as to the durability of a particular appliance; the latter affects the rate of depreciation. The two methods generally adopted are: (1) To assume a definite rate of depreciation on either the plant and machinery as a whole or definite rates for each part thereof, and to deduct this from either the original cost or the book value. (2) To value each individual part of the plant and machinery each year and write off the difference in value from that of the previous valuation. The Inland Revenue officers usually employ a third method, based on renewals.

All these methods are faulty. In the first the result is hazardous, especially if based on a single rate of depreciation on the whole plant and machinery, because different parts depreciate at different rates, and no single figure or 'average' can be accurate. Even if the plant and machinery are divided into groups or each individual item is taken separately errors may still occur, as it is by no means easy to find an accurate rate of depreciation for some appliances. In the second method an independent valuer is essential, and the method is therefore costly. A common device is to use the first method, applied to the plant and machinery after dividing it into five or six groups, and to adjust this by a revaluation by an expert every five years. This is probably the best compromise between accuracy and cheapness.

When the first method alone is used, a distinction must be made in the rate of depreciation, according as this is deducted from the original cost of the appliance or from its diminished value (see *ante*).

Fire Insurance and Depreciation.—Whilst it is a sound, general policy to write as much off for depreciation as possible, such a course has an adverse effect on insurance against fire, as the value in the case of a fire would be affected in the claim for replacement. It is usual in some offices to append a declaration on the face of the policy that the depreciation written off in the books shall not be taken for the purpose of assessing a fire loss. Usually the assured is covered for the value of the plant at the time of the fire, and that the original cost of the plant, less depreciation, is not necessarily the basis of the claim. There appears to be no scale of depreciation in force for different kinds of plant recognised by the insurance companies, but these losses are generally settled as between the assessors and surveyors acting for both parties, or, failing their agreement, by arbitration: no special rates are applicable, but each case is settled on its merits. The principal factor appears to be the possession of definite and specific information on the value and cost of the plant, and the rate of depreciation should not in any way govern the claim in case of fire.

It is a general provision in fire insurances and policies that the company may elect to replace the plant; instances of this have rarely occurred, if ever, and probably the replacement clause was never intended as other than a protection to the insurance company.

Depreciation and Income-Tax.—The rate of depreciation allowed by the inspectors appointed under the Income-tax Acts differs considerably in different localities. For instance, the rate of depreciation allowed to engineers in Leicester is 7½ per cent. on the full value, while in Cardiff the rate is only 5 per cent. on the diminished value. Hosiery machinery in Leicester obtains 7½ per cent. as against 5 per cent. on lace machinery in Nottingham. Dyers' machinery in Leicester can get 10½ per cent., if justified on inquiry. Generally speaking, a distinction is made between motive power and process plant, and the general practice assumes 5 per cent. on motive power and 7½ per cent. to 10 per cent. on process plant; these allowances are in respect of both deterioration and renewals.

The Inland Revenue authorities have now reverted, in a number of cases, to the basis of original cost, and where, say, 5 per cent. is allowed on original cost, there is an alternative rate of 7½ per cent. allowed on diminishing value.

On *Fixtures* no allowance for depreciation is made, unless they are included under the head of plant. Any replacements are allowed in full against the year's working.

Renewals.—The practice adopted by the income-tax authorities provides for the charging up of renewals to capital account where depreciation is allowed, and they usually decline to allow both renewals and depreciation out of the year's profits. They will, however, permit, as an alternative to the allowance for wear and tear and obsolescence of plant and machinery, the cost of renewing

plant and machinery, under Schedule D. When this course is adopted, the amount to be allowed is the actual cost of the new plant and machinery (excluding any part of such cost which is attributable to additions or improvements, *i.e.* to an increase in capital) after deducting the scrap value or realised price of the plant and machinery replaced.

Example (*a*).—A machine which originally cost 1,000*l.* is worn out and replaced by a machine of similar power or size or capacity which now costs 1,500*l.* The whole of this expense of 1,500*l.* less, say, 100*l.*, the scrap value of the old machine (making a net amount of 1400*l.*) is allowable from the profits of the year in which it is incurred.

Example (*b*).—A machine which originally cost 1,000*l.* is worn out and replaced by one of greater power or size or capacity costing 2,500*l.* The amount to be allowed as an expense is in this case not the full 2,500*l.*, but only the cost of replacing the old machine by one of similar power or capacity, say, 1,500*l.*, less the scrap value of the old machine.

Although this method of allowance is alternative to the wear and tear allowance for the same class of plant, the two principles may run concurrently for different classes of assets in the same business. For example, the wear and tear allowance may be applied to fixed machinery, and the renewal method used for loose plant.

Example (*c*).—Assuming the total written down value of the trader's plant and machinery before the sale of the obsolete machine to be 10,000*l.*, the new machine to cost 1,400*l.* and the old one to be sold for 400*l.*, future wear and tear allowances will be made upon a value of 11,000*l.*, thus :—

	£
Written down value of total plant, etc.	10,000
Deduct written down value of the obsolete machine	400
	£9,600
Add cost of new machine	1,400
	£11,000

The obsolescence allowance is not made in quite the same way as the wear and tear allowance, for the latter is by statute an allowance from the assessment *after* the three years' average is struck. Thus the wear and tear allowance applicable to the year 1925–6 would be given as a deduction from the gross assessment for 1925–6 as follows :—

Trading profits (before allowing wear and tear)—	£
1922—Loss	5,000
1923—Profit	10,000
1924—Profit	13,000
	3)18,000
Gross assessment, 1925–6	£6,000
(If the total wear and tear allowance due for the year 1925–6 were 6,500*l.* a sum of 6,000*l.* would be allowed against the 1925–6 assessment, and the balance of 500*l.* carried forward for deduction in future years.)	
Wear and tear allowance	6,000
Net amount on which tax is payable for 1925–6	nil

An allowance for obsolescence in 1925 of, say, 10,000*l.* would, however, be a deduction from the commercial profits of 1925, turning them from a profit of, say, 9,800*l.* to a loss of 200*l.* The first assessment to be affected would be that of 1926–7, as follows :

	£
Profits 1923	10,000
1924	13,000
1925—Loss	200
	3)22,800
Gross assessment, 1926–7	£7,600
Less—	
Allowance for wear and tear, say, 6,800*l.*, for 1926–7, plus the unexhausted balance carried forward from 1925–6, 500*l.*	7,300
Net amount on which tax is payable for 1926–7	£300

The business year 1925 would also have come into the average for the tax years 1927–8 and 1928–9, by which time the allowance would have had its full effect, only the 'three years' average' was stopped in 1927. After that date (except by special arrangement) only one year's profits are taken in the assessment.

This 'renewal allowance' has been made statutory by each Finance Act since 1918.

SECTION XLVII

LEGAL NOTES FOR ENGINEERS

Contributed by W. Valentine Ball, O.B.E., M.A., Barrister-at-Law, A Master of the Supreme Court.

Author of 'The Law Affecting Engineers' (Constable & Co.); 'The National Form of Building Contract' (published by The Local Government Journal), and Joint Editor of 'Emden's Building Contracts,' 4th Edition (Butterworth & Co.)

SECTION XLVII

LEGAL NOTES FOR ENGINEERS.*

(Contributed by W. Valentine Ball, O.B.E., M.A., Barrister-at-Law, A Master of the Supreme Court.)

(1) LEGAL STATUS OF AN ENGINEER. (2) FEES. (3) EMPLOYMENT OF AN ENGINEER. (i.) *Generally*; (ii.) *Employment Abroad*; (iii.) *Wrongful Dismissal*; (iv.) *The Restrictive Covenant*, (v.) *Engineers and Compensation for Accidents*; (vi.) *Engineers and the National Insurance Act*; (vii.) *Effect of War on Contracts.* (4) SECRET COMMISSIONS. (5) DISCLOSURE OF SECRETS. (6) RIGHTS OF AN ENGINEER TO THE INVENTIONS OF A SERVANT. (7) THE ENGINEER AS WITNESS. (i.) *Generally*; (ii.) *Arrangements as to Fees*; (iii.) *Evidence before Parliamentary Committees.* (8) LIABILITY FOR NEGLIGENCE. (9) RIGHTS, POWERS, AND DUTIES OF AN ENGINEER UNDER A CONTRACT FOR WORKS. (i.) *Generally*; (ii.) *Specifications*; (iii.) *Plans and Drawings*; (iv.) *Extras*; (v.) *Certificates*; (vi.) *Penalties and Bonuses*; (vii.) *Defects, Repairs, and Maintenance*; (viii.) *Subcontractors and Specialists*; (ix.) *Whether the Employer's Engineer can act as Arbitrator in Relation to Disputes Arising under a Contract.* (10) THE ENGINEER AS ARBITRATOR. (i.) *Generally*; (ii.) *Who may be Arbitrator*; (iii.) *Proceedings before the Arbitrator*; (iv.) *The Award*; (v.) *Time for Making the Award*; (vi.) *The Fees of an Arbitrator*; (vii.) *Stating a Case for the Opinion of the Court*; (viii.) *Costs of a Reference.* (11) NOTES ON SALE AND PURCHASE OF MACHINERY.

(1) LEGAL STATUS OF AN ENGINEER.

Any person may describe himself or practise as an engineer, as the word engineer is not a term of art in the legal sense. Although the Institution of Civil Engineers may make rules of professional etiquette to be observed by its members, compliance with such rules will not be enforced in a court of law, save in so far as they involve a restatement of the ordinary law. For instance a rule which states that no consulting engineer shall advertise could not be enforced, whereas infringement of a rule that 'he shall not pay by commission or otherwise anyone who introduces clients' might offend against the common law (*Panama Telegraph Co.* v. *India Rubber Co.* (1875) L. R. 10 Ch. 515) or against the Secret Commissions Act.

(2) FEES.

If an engineer is consulted, there is an implied contract to pay him reasonable remuneration (*Manson* v. *Baillie* (1855) 2 Mac. H. L. Cas. 80). It is more satisfactory, however, to provide for payment of fees beforehand. In the case of a contract to design and supervise erection of works it is well to provide for payment of $\frac{1}{3}$ on signing the contract, $\frac{1}{3}$ when half the contract price has been paid to the contractor, and $\frac{1}{3}$ when the contractor has been fully paid. Provision should also be made for (1) payment for plans and drawings in case the works are abandoned; (2) travelling and hotel expenses. There is, of course, no fixed scale of remuneration for the engineer, but in deciding what is a reasonable charge, the Court would have regard to (i.) the standing of the engineer; (ii.) the nature and extent of the work undertaken and carried out. It is no answer to a claim for fees (*a*) that a particular undertaking has proved to be a failure if the failure was not due to any fault of the engineer—as where, for instance, an engineer is employed merely to *supervise* the erection of a dam which bursts on completion; or where an engineer is employed to draw plans for a newly invented machine which fails to work (*aliter* if the employer was relying on the engineer's skill and judgment: *Duncan* v. *Blundell* (1820) 3 Stark. N.P. 6); (*b*) that the work in question is not completed, if the failure to complete is not due to the engineer. Where an engineer is to be paid on completion and the work is abandoned before the time, the engineer is entitled to what is due for services rendered, and to what he has lost by not being allowed to complete the contract (*Horton* v. *Hemsley* (1908) *Times*, February 19).

* See also 'LEGAL POINTS FOR ROAD ENGINEERS,' p. 805.

(3) EMPLOYMENT OF AN ENGINEER.

(i.) **Generally.**—Where an engineer is to be employed for more than a year certain, the agreement must be in writing; and this is so, even if the employment is terminable at any time by six months' notice on either side (*Hanau* v. *Ehrlich* (1912), A.C. 39). The document must set forth all the terms. It is safer, however, to have the terms of an agreement always put into writing. Special care should be taken to (*a*) specify the times when the salary is to be paid; (*b*) provide for the contingency of illness, as illness does not necessarily determine the contract, nor will it justify dismissal without regular notice, unless the employee is so smitten with disease that he can never be expected to work again (*Cuckson* v. *Stones* (1858) 1 E. & E. 248); (*c*) provide for the notice which may be given on either side to determine the contract. If nothing is specified in the agreement, an engineer employed at a yearly salary is entitled to a year's notice (*Buckingham* v. *Surrey and Hants Canal Co.* (1882) 46 L. T. 885). An engineer wrongfully quitting his employment without notice forfeits the salary due for the part of the current year which he has served. The fact that a contract of employment for an indefinite period contains no express term as to notice to be given for its determination does not exclude the implication that such a notice is required (*Payzu* v. *Hannaford* 34 T. L. R. 442). The suspension of servant from his duties which prevents his earning his commission may amount to a wrongful dismissal (*Rubel* v. *Vos*, 34 T. L. R. 171). Dismissal without notice is only justifiable in a case of gross misconduct. If the 'employer' is a company or a municipal corporation or other local authority it is safer to insist that the contract be under seal. The Public Health Act, 1875, s. 174 (1) provides that every contract made by an urban authority whereof the value or amount exceeds 50*l.* shall be in writing and sealed with the common seal of such authority. A surveyor who prepared plans for a local board under a verbal contract was held entitled to recover nothing (*Hunt* v. *Wimbledon Local Board* (1878) L. R. 4 C. D. D. 48). Close examination of a contract between an engineer and a local authority may, however, show that it is not within this section (see *Douglass* v. *Rhyl U.D.C.* (1913) 2 Ch. 407). Where the engineer is in the employment of a local authority he must have no interest in any contract into which that body enters (see *Melliss* v. *Shirley Local Board* (1885) L. R. 14 Q.B.D. 911). An attempt was recently made to raise the question whether a consulting engineer is liable to pay excess profits duty under s. 39 of the Finance Act, 1915, but the Court of Chancery refused to decide the point, leaving it to the King's Bench Division (*Smeeton* v. *Attorney-General* 35 T. L. R. 706).

(ii.) **Employment Abroad.**—Where an engineer is about to accept employment abroad, he should be careful to see that provision is made for the payment of travelling and other expenses. No agreement to pay travelling expenses would be implied from an undertaking, say, to employ an engineer at a salary of 1,000*l.* a year at Malacca as from January 1, 1913. It is also well to provide in the agreement that any disputes which may arise shall be determined either by arbitration or according to English law.

(iii.) **Wrongful Dismissal.**—If an engineer is wrongfully dismissed, it is his duty to reduce the damages as far as possible by taking other employment if he can procure it (see *Storey* v. *Fulham Steel Works* (1908) 23 T. L. R. 306). The damages are then ascertained by subtracting what he has earned from what he would have earned.

(iv.) **The Restrictive Covenant.**—When employing an assistant, an engineer may find it necessary to bind him not to set up close by in competition. A restrictive covenant is legal, if it is not too wide; it must be only what is reasonably necessary for the protection of the parties. A covenant to prevent a dentist practising within 200 miles of York was held to be too wide (*Horner* v. *Graves*, 7 Bing. 735). On the other hand, a covenant which bound a canvasser not to enter an employment 'within twenty-five miles of London where the plaintiffs carry on business' was held by the House of Lords to be unreasonable (*Provident Clothing and Supply Co.* v. *Mason* (1913) 29 T. L. R. 727). Care should be taken not to make the restriction perpetual unless that is absolutely necessary, for the Court criticises a perpetual covenant more closely (*Eastes* v. *Russ* (1915) 30 T. L. R. 237). In a recent case the validity of a covenant affecting a man who was employed as works engineer at a bottleworks was considered (*Forsters* v. *Suggett* 35 T. L. R. 87).

(v.) **Engineers and Compensation for Accidents.**—An engineer whose remuneration (*e.g.* money, board and lodging, etc.) amounts to less than 250*l.* in the service of an employer is probably entitled to the benefits of the Workmen's Compensation Act, 1906.

(vi.) **Engineers and the National Insurance Act.**—A nice question may arise as to whether, say, a station engineer must be treated as an employed contributor within the meaning of the National Insurance Act, 1911. That act covers employment in any contract of service subject to the proviso that persons earning more than 160*l.** otherwise than in manual labour need not be insured. It is submitted that the station engineer earning less than 160*l.* must be insured, but that the consulting engineer who receives an annual fee of 100*l.* for advising a firm or company need not be insured. His is a contract not 'of service' but 'for services'—a distinction which has been drawn in the Court of Appeal.

* By the National Health Insurance Act, 1919, now raised to 250*l.*

(vii.) **Effect of War on Contracts.**—Contracts entered into during the war, between British citizens and the citizens of States at war with Great Britain, were illegal and could not be enforced, unless a licence to trade was granted to one of the belligerents. Subject, however, to certain exceptions, contracts entered into by the citizens of one belligerent State with citizens of another belligerent State before the outbreak of hostilities between their respective states are not dissolved by the outbreak of war but suspended until the war is over. During suspension no performance of the contract is permitted, nor will any action on it be entertained in English Courts, even though the cause of action arose before the war. But the war being now over the mutual obligations of performance and the rights of action revive. The exceptions are (*a*) Contracts entered into before the outbreak of hostilities which will inure to the aid of the enemy or which involve any dealing with the enemy (see *Furtado* v. *Rogers*, 3 Bos. & P. 91); and (*b*) Contracts entered into before the outbreak of hostilities which from their nature cannot be merely suspended (*Griswold* v. *Waddington* (1818) 16 Johnson's Rep. 438).

(4) SECRET COMMISSIONS.

The receipt of a secret commission or a bribe by an engineer would clearly justify his dismissal (*Boston Deep Sea Fishing Co.* v. *Ansell* (1888) 39 Ch. D. 339). In such a case there is a presumption that he was influenced, against his employers' interest, by the bribe (see *Hovenden* v. *Millhoff* (1900) 83 L. T. 11).

(5) DISCLOSURE OF SECRETS.

An engineer may be employed to do work of a confidential nature for others; or he may have to employ workmen to do confidential work for him (*e.g.* by employing a workman to make a model of a new and patentable machine). The law implies an agreement by the servant to keep his master's secrets, and he may be restrained by injunction from disclosing them (*Alperton Rubber Co.* v. *Manning and Others* (1917) 116 L. T. 499; 33 T. L. R. 205).

(6) RIGHTS OF AN ENGINEER TO THE INVENTIONS OF A SERVANT.

If a servant invents a machine in his employer's time and even when using his employer's materials, the invention does not become the property of the employer so as to prevent the servant taking out a patent for it (*Heald's Case*, 8 R. P. C. 430). But if the servant were to steal an idea and endeavour to patent it either before or after the termination of the service, the employer could oppose the grant of a patent in respect of it (*Thwaites' Application*, 9 R. P. C. 515). And if the servant obtains a grant of a patent in respect of the invention, he can only hold it as trustee for his employers (*British Reinforced Concrete Engineering Co.* v. *Lind* (1917) 33 T. L. R. 170). The engineer when employing a servant should take care to provide, by the agreement, that the inventions of the servant shall belong to him; but when himself entering into a contract of service he should be careful to sign nothing which will abrogate his rights.

(7) THE ENGINEER AS WITNESS.

(i.) **Generally.**—As the engineer frequently comes into contact with the law and the lawyers in the capacity of a *witness*, a few notes of a practical character on the duties of a witness may be found useful.

When invited to give evidence as an expert the engineer should: (*a*) arrange for a qualifying fee to be paid in any event; (*b*) examine the plans and documents, and, if necessary, obtain a view of the *locus in quo* before consenting to give evidence; (*c*) warn the parties consulting him of all the difficulties which are manifest to him; (*d*) ascertain, if possible, the contentions which are going to be put forward by the other side, and make himself familiar with any views which they may have published upon the matters in dispute. Having consented to give evidence, the engineer should (*a*) be ready to satisfy the lawyers with regard to any technical point which may be raised in consultation; (*b*) listen to the arguments and evidence in Court, and be prepared to deal with any points made by witnesses on the other side; (*c*) bring with him any entries in his diary or any notes which he may have made *at the time* with reference to the matters in dispute, for he may use such notes to refresh his memory. Thus, if an engineer has to report as to the condition of a structure, he may use in the witness box the notes which he made on the spot. But he could not use a copy of such notes unless he was prepared to produce the original; (*d*) make and bring to court a plan or model of the structure or machine under discussion, as this will save much wordy explanation; (*e*) search in libraries and in the published proceedings of the various institutions for any books and papers dealing with the matters in hand—especially any papers written by himself, in order that he may not be confronted with an adverse opinion given on a former occasion. A witness should bear in mind that it is his duty to state facts and express opinions, not to advocate the cause. As soon as he appears to be taking a biased view or attempting to fight the case it is more than likely that the tribunal will pay little heed to his evidence. A candid answer to an awkward question is often less dangerous than a long and evasive statement. In *Crosfield and Sons, Ltd.* v. *Techno-Chemical Laboratories Ltd.* (1913, 29 T. L. R. 378) Neville, J., expressed some views as to the function of an expert witness which may be thus summarised:—

(*a*) It is not competent in any action for witnesses to express their opinion upon any of the issues, whether of law or fact, which the Court or a jury has to determine.

(*b*) In patent cases, expert evidence is often necessary (i) to explain words or terms of science or art, or to inform the Court in case the import of a word in a document to be construed differs from its popular meaning; (ii) to instruct the Court in the laws of science; (iii) to describe the state of public knowledge at the date of the patent. 'It is rare,' added his lordship, 'to find any substantial difference of opinion between eminent experts upon matters of science whenever it is possible to dissociate the question from immediate connection with the issues in the action.'

(ii.) **Arrangements as to Fees.**—On being *subpœnaed* one is bound to attend as a witness provided sufficient conduct money is paid with the subpœna. Failure to attend might lead to an action for damages, while in the County Court the judge has power to fine a witness for non-attendance. A witness may refuse to give evidence until his expenses have been paid (*Newton* v. *Harland* (1840) 1 M. & G. 956). It should be noticed that the person liable to pay the fees is the party to the litigation, not the solicitor, unless he has expressly made himself liable (*Lee* v. *Everest* (1857) 26 L. J. Ex. 334). In order to save trouble it is best to arrange for and if possible secure payment of fees in advance. The fees 'allowed on taxation,' that is to say, the fees which an unsuccessful litigant will be ordered to pay in respect of witnesses called by the other side, are very small, but the party calling the witness will have to pay his agreed fee whatever it is. Where a case is tried at assizes in the town where the engineer lives or in London (when the engineer lives in London), the fee allowed is 1*l.* 1*s.* *per diem*, or where the engineer lives away from the town 1*l.* 1*s.* to 3*l.* 3*s.* But the taxing masters may also allow a qualifying fee of so much a day varying with the magnitude of the case. In 1875 a fee of 7*l.* 7*s.* was not considered excessive payment to a scientific witness. It is probable that a larger sum would be allowed at the present day. In addition he is allowed the travelling expenses reasonably and actually paid. In County Courts the fee allowed for qualifying to give evidence on Scale B is 1*l.* 1*s.* to 3*l.* 3*s.*; on Scale C, 1*l.* 1*s.* to 5*l.* 5*s.*; for attending Court on trial (*per diem*), Scale B, 1*l.* 1*s.* to 2*l.* 2*s.*; Scale C, 1*l.* 1*s.* to 3*l.* 3*s.*

The above scales were fixed before the war, and have not been altered. So far as they can the taxing masters will probably grant the maximum owing to high prices.

(iii.) **Evidence before Parliamentary Committees.**—When an engineer is summoned to appear as a witness before a committee of either House of Parliament he looks for his fees to the party who summons him—whether he is the promoter or an opponent. According to May's 'Parliamentary Practice' (1906) p. 434, an engineer summoned as a witness before a committee should report himself to the committee clerk on his arrival in London, or he will not be allowed his expenses for residence prior to the day of making his report; 3*l.* 3*s.* a day is the parliamentary allowance, but of course as between the engineer and the party summoning him the *quantum* of the fee is a matter of agreement.

(8) LIABILITY FOR NEGLIGENCE.

The liability of an engineer for negligence is similar to that of any other professional man. To render him liable it is not enough that there has been a less degree of skill than some other professional man might have shown. A fair average degree of skill is all that can be insisted upon (*Lamphier* v. *Phipos* (1838) 8 Car. & P. 475). If an engineer were so careless in the preparation of a tender that the cost of the works was grossly underestimated, he would probably be liable to pay damages, and he certainly could not recover his fees (*Moneypenny* v. *Hartland* (1826) 2 C. & P. 379). An engineer should be acquainted with any local bye-laws appertaining to the work in hand (*Monks* v. *Dillon* (1884) 12 L. R. Ir. 321). On the principle of *respondeat superior* an engineer is responsible for the acts or defaults of assistants employed by him (*Mackersy* v. *Ramsays* (1842) 9 C. & F. 818). The question 'To whom is the engineer liable for negligence?' depends upon the conditions of employment. If he is engineer in relation to a large contract he is not liable for anything done by him in his capacity as arbitrator between the employer and the contractor; but he is liable for damage resulting from negligence in supervision, *e.g.*, failure to examine and test work before it is hidden from view (*Leicester Guardians* v. *Trollope* (1911) 75 J. P. 197). The contractor, however, could not sue the engineer for an error in the specifications on the basis of which he made his tender. Where, however, the 'quantities' are prepared by the engineer, and his fees for their preparation are paid by the contractor, it is conceived that he could be sued for damages resulting from an error in those quantities (*Bolt* v. *Thomas*, 'The Law Affecting Engineers,' p. 58). If an engineer order extras without authority, the contractor may possibly sue him for damages for breach of warranty of authority (*Randall* v. *Trimen* (1856) 18 C.B. 786). The amount of damages recoverable for negligence is to be measured by the loss which the plaintiff has suffered. In *Saunders* v. *Broadstairs Local Board* (1890) 2 H. B. C. 160, two engineers claimed fees for preparing surveys, obtaining tenders, and superintending the execution of a contract for certain drainage works. The board counterclaimed for negligence and were awarded 2,046*l.*, the amount overpaid to the contractor by reason of the negligence of the engineers in over certifying the quantities; 2,400*l.* estimated cost of doing bad work over again; 240*l.* actual cost of repairs already done to defective work. Damages recovered by a workman against his employer for an accident might also be recovered from the engineer if it were shown that the accident was caused by the engineer's negligence (*Mosdell* v. *Mitchell*, 'Times,' January 20, 1891).

(9) RIGHTS, POWERS, AND DUTIES OF AN ENGINEER UNDER A CONTRACT FOR WORKS.

(i.) **Generally.**—Common forms of contract for large works usually set forth the powers, etc., of the engineer very clearly. The preparation of the contract is generally left to a lawyer, but the engineer should be on his guard against allowing a common printed form to be applied indiscriminately to the construction of works of a special nature. When difficulties arise it may be found that the common form does not provide for their elucidation.

(ii.) **Specifications.**—The contract should contain a clause providing that the employer will not be responsible for any mistakes or inaccuracies in the specifications which form part of the contract. Such a clause will, in the absence of fraud, afford him protection (*Pearson* v. *Dublin Corporation* (1907) A. C. 357). There should also be a clause calling the would-be contractor's attention to the fact that he must make surveys and borings for himself before making his tender. In that case, if unforeseen difficulties are met with the employer will not be responsible (*Thorn* v. *Mayor of London* (1876) L. R. 1 A.C. 120). Again, where a man undertakes to make *e.g.* sound hydraulic cylinders according to a specification, capable of withstanding a certain pressure, he takes upon himself the risk of the cylinders being able to withstand the named pressure when made according to the specification (*Hydraulic Co.* v. *Spencer* (1886) 2 T. L. R. 554). Carelessness in the preparation of a specification may involve the employer in added expense, for which the engineer may be liable (*Moneypenny* v. *Hartland* (1828) 2 C. & P. 378).

(iii.) **Plans and Drawings.**—These form part of the contract, and may, in the absence of a disclaiming clause, operate as a warranty that dimensions, measurements, etc., are correct. A clause disclaiming responsibility for accuracy should therefore be inserted in the contract. The engineer has no implied authority to alter plans and drawings so as to increase or lessen the burden imposed upon the contractor (*Cooper* v. *Langdon* (1841) 9 M. & W. 60). Delay in supplying the necessary plans and drawings may excuse the contractor from carrying out the work within the contract time (*Roberts* v. *Bury Commissioners* (1869) L. R. 5 C. P. 310). It is for the engineer who prepares them to see that they conform to local bye-laws (*Cubitt* v. *Smith* (1864) 11 L. T. 298). Plans and drawings made for the purpose of carrying out works are the property of the employer—not of the engineer (*Gibbon* v. *Pease* (1905) 1 K.B. 810). As to copyright in plans, see the Copyright Act, 1911, s. 5.

(iv.) **Extras.**—The duty of deciding what are 'extras' within the meaning of the contract is usually entrusted to the engineer. He has no implied authority to order extras (*Cooper* v. *Langdon* (1841) 9 M. & W. 60), although an agreement to work *to the satisfaction* of an engineer has been held to give him implied authority to order extras (*Robertson* v. *Jarvie* (1910) 45 S. L. R. 260). It has been held, however, that where the plaintiffs were employed by an architect (whose functions, for this purpose, correspond to those of an engineer) to supply door handles and door furniture for a building, and shortly before the delivery of the goods he informed the defendants, who were the builders, that the goods were being supplied by the plaintiffs, the defendants who used the goods in the building were liable to pay for them (*Ramsden* v. *Chessum* (1914) 78 J. P. 49). Extras should be authorised in the manner provided by the contract, which usually provides that all extras shall be ordered in writing (*Russell* v. *Saida Baudeira* (1862) 13 C. B. N. S. 149); but, in the case of a contract with a local authority, which must be under seal, the order for extras need not be under seal (*Williams* v. *Barmouth Urban Council* (1897) 77 L. T. 383). If a written certificate is rendered necessary by the contract, nothing else will suffice; but in a recent case a contractor proceeded with extra work as required by an engineer without any written order. On his claiming payment, an arbitrator found that the engineer was wrong and unreasonable, and that the work and materials required by him were not included in the contract. After much litigation the House of Lords eventually held that this decision was correct (*Brodie* v. *Cardiff Corporation* (1919) 120 L. T. 417). Although the whole scheme of works cannot be altered by virtue of the extra clause (*R.* v. *Peto*, 1 Y. & J. 37) power to *vary* the work will give the engineer authority to substitute one piece of machinery for another of which it is well known to be the mechanical equivalent (*Stevens* v. *Mewes & Davies*, Court of Appeal, June 7, 1910; Emden's 'Building Contracts,' Supplement 1911). The engineer should therefore see that he has power to *vary* the work. The engineer's decision as to what are extras may or may not be subject to revision in accordance with the arbitration clause. So far as the contractor is concerned, the fact that the engineer has given his final certificate (see *sub tit. Certificates, post*) may involve a final decision as to what is and what is not an extra (*Connor* v. *Belfast Water Commissioners* (1871) 5 L. R. Ir. C. L. 55). Power to extend the time for completion is generally given to the engineer. It may be that owing to the action of the Government acting under the Defence of the Realm Acts, the performance of a contract for works becomes illegal during the continuance of the War. In such a case it is conceived that no extension of time by the engineer will avail to keep the contract alive (see *Metropolitan Water Board* v. *Dick, Kerr & Co.*, 34 T. L. R. 111).

(v.) **Certificates.**—It is the duty of an engineer in relation to a contract for large works to grant or withhold the certificates upon which the contractor is paid. 'Progress certificates' are given from time to time as the work proceeds. They generally authorise payment to the extent of

80 per cent. upon the contract value of the work done from time to time. The remaining 20 per cent. is kept back usually, as to 15 per cent. until the final certificate is granted and as to 5 per cent. until the end of some stated period after the final certificate. This 20 per cent. is called the retention money (see *West Yorkshire Bank Ltd.* v. *Isherwood Bros.* (1912) 28 T. L. R. 593). The 'final certificate' is granted when the work is finished to the satisfaction of the engineer, and the contractor can sue for nothing until it has been granted (*Wallace* v. *Brandon and Byshottles U.D.C.* (1903) 2 H. B. C. 392). In deciding as to certificates the engineer acts as an arbitrator, and his decisions cannot be called in question (*Wadsworth* v. *Smith* (1871) L. R. 6 Q.B. 332); nor can he be compelled, and is better advised not to give reasons for his decision (*Stevenson* v. *Watson* (1879) L. R. 4 C. P. D. 148). No action lies against him for negligence in relation to certificates (*ib.*) (but see the case of *Goddard* v. *Ferguson*, *infra*). In exercising his discretion he must act as an arbitrator between employer and contractor (*Chambers* v. *Goldthorpe* (1901) 1 K.B. 624). It may, however, be that the decision of the engineer as to a certificate is subject to the arbitration clause, which has been held to be the case in relation to the form of contract approved by the Royal Institute of British Architects (*Robins* v. *Goddard* (1905) 1 K.B. 294). A fraudulent agreement between the employer and the engineer would however affect the validity of a certificate (*Kellett* v. *New Mills U.D.C.* (1900) 2 H. B. C. 330). The certificate of the engineer may be made a condition precedent to the contractor's right of action against the employer. If so an action cannot be maintained unless there has been improper dealing between the engineer and the employer (*Eaglesham* v. *McMaster* (1920) 2 K. B. 169). The statement that an engineer is not liable for negligence in relation to a certificate does not appear to be supported by the case of *Goddard* v. *Ferguson* (referred to by Mr. Saxon Snell in a paper read by him at the Royal Institute of British Architects, April 15, 1912). It was there held that an architect who grants a certificate which is successfully challenged by an employer in an action brought against him by a builder to recover the amount so certified to be due to him, is liable to repay to the employer the costs incurred by him in resisting the builder's claim. The Official Referee held the architect liable on the ground that when acting as agent for the building owner in granting certificates, he must be held responsible for the reasonable and probable consequences of giving a certificate subsequently held to be inaccurate or excessive. Certificates should always be given in writing in a formal manner. No engineer should pass any contract which does not contain a provision to this effect. As to when an engineer is disqualified from granting certificates, see paragraph ix., *infra*. An engineer has no right to delegate the power to grant a certificate to a subordinate, *e.g.* to the resident engineer (*Freeman & Sons* v. *Middleton Electric Traction Co.*, per Hamilton, J., July 15, 1910; Court of Appeal, January, 1911; Emden's 'Building Contracts,' Supplement, 1911).

(vi.) **Penalties and Bonuses.**—The question whether the contractor must pay penalties or not depends almost entirely upon the engineer. Penalties are imposed if the work is not carried out in accordance with the provisions of the contract as to time. The fact that extras are ordered will excuse the contractor from compliance with the conditions as to time (*Dodd* v. *Churton* (1897) 1 Q.B. 562), but the jurisdiction of the engineer does not extend to deciding this point (*Gallivan* v. *Killarney Urban Council* (1912) 2 Ir. R. 356). To avoid complication, however, it is best to insert a clause in the contract giving the engineer power to extend the time. With regard to the penalty clause generally nice questions sometimes arise as to whether it is capable of enforcement. If it is unreasonable on the ground that the punishment is too severe, the Court may refuse to enforce it; and it is for this reason that the words 'the sums to be regarded as liquidated damages and not as a penalty' are usually inserted after the sum named. The breach of an engineering contract involves damage of so uncertain a nature that the courts will generally treat the sum which the parties themselves have named as liquidated damages. Penalties will not be imposed if (*a*) the delay was caused by the act or default of the employer (*Thornhill* v. *Neats* (1860) 8 C. B. N. S. 831); (*b*) if there is delay in setting out the site or in delivering plans (*Roberts* v. *Bury Improvement Commissioners* (1870) L. R. 5 C. P. 310). The fact that the contractor has been delayed by a strike of his workmen, however, affords no excuse for delay (*Budgett* v. *Rimington & Co.* (1890) 25 Q.B. D. 320), nor, apparently, is the employer to be held liable for the acts of third parties causing delay (*Porter* v. *Tottenham U.C.* (1915) 1 K. B. 776). While a penalty clause is usually optional, it is obligatory in contracts made with certain local authorities (see Public Health Act (1875) s. 174 (2)). A bonus clause is sometimes inserted by virtue of which a contractor is enabled so much extra for expedition. If a contract contains such a clause, and the engineer has power to extend the time, it seems that his power to extend must be exercised not to enable the contractor to earn the bonus but only to avoid penalties (*Ware* v. *Lyttelton Harbour Board* (1882) 1 N. Z. R. 191).

(vii.) **Defects, Repairs, and Maintenance.**—In contracts relating to the erection of machinery clauses should be inserted providing for any defects which appear either before or after the issue of the final certificate. A useful form of this clause will be found in the printed conditions of contract issued by the Institution of Electrical Engineers. Its importance will be recognised when it is pointed out that when it is absent the final certificate of the engineer may possibly bar any further claim by the employer (*Lord Bateman* v. *Thompson* (1875) 2 H. B. C. 23). The time for the remedy of defects should be prolonged as much as possible, inasmuch as the very fact of there being a defects clause impliedly releases the contractor from liability for defects appearing after the stated time (*Sharp* v. *Great Western Railway Co.* (1841) 11 L. J. Ex. 17). The contractor can only be called upon to repair and maintain when compelled to do so by a repairing clause and a maintenance clause. The employer must give notice of want of repair. Mainten-

ance should be provided for in cases where the machinery or work is of a special character which is best known to the contractor. In the absence of any clause relating to defects and maintenance, it does not follow that on payment of the full price the employer thereby waives all claim for damages for work improperly done. It is a question of fact having regard to all the circumstances of the case whether the settlement was final and complete.

(viii.) **Subcontractors and Specialists.**—Most modern contracts involve the employment of subcontractors or specialists. A clause should be inserted in the head contract prohibiting the employment of any subcontractor or specialist unless approved by the engineer. In the absence of such a clause, the contractor might, possibly, farm out portions of the work to all and sundry (*British Waggon Co.* v. *Lea* (1880) 5 Q. B. D. 149). The engineer, apparently, has no implied authority to employ subcontractors (*Cowan* v. *Goderich* (1859) 10 U. C. C. P. 87). It is often well to specify the names of manufacturers of the raw materials which are to be used in the body of the contract. In order to preserve his right to supervise the work of any subcontractor or specialist, the engineer should secure the insertion in the head contract of a clause providing that payments to subcontractors shall be made by the contractor only upon the certificates of the engineer. It is also well to secure the insertion of a clause to the effect that, in the event of the contractor becoming insolvent, the subcontractor or specialist may be paid directly by the employer. All responsibility for delay or negligence on the part of a subcontractor is generally, by a special clause, placed upon the contractor (see, generally, *Crittall* v. *L. C. C.* (1910) 75 J. P. 203; *Hampton* v. *Glamorgan County Council* (1916) 115 L. T. R. 426, and the case of *Ramsden* v. *Chessum*, cited, *supra*, s. (9) (v.) (i.)).

(ix.) **Whether the Employer's Engineer can act as Arbitrator in Relation to Disputes Arising under a Contract.**—The position of the engineer in relation to a large contract has been rendered very difficult by certain recent decisions of the courts. In theory he is agent for the employer in the preparation of plans and specifications and in the supervision of the work, and he is arbitrator or *quasi* arbitrator between the employer and contractor in granting certificates, approving work done, granting extensions of time, etc. Sometimes he is made sole arbitrator to decide all disputes between the employer and the contractor, and a serious question has arisen in several recent cases as to how far a contractor can be forced to accept his decision whether in the matter of granting certificates, etc., or as arbitrator. In *Jackson* v. *Barry Railway Co.* (1893) 1 Ch. 238, it was held that the fact of the employer's engineer having expressed a view of the matter in dispute hostile to the contractor was not a sufficient justification for refusing to allow him to act as arbitrator in relation to that dispute. The Court of Appeal pointed out that the contractors had agreed to this form of reference, and what they relied on was the professional honour, practice, and intelligence of the engineer. There was nothing in the circumstances of the case to render it improbable that he would not arrive at an honest decision.

In *Ives* v. *Willans* (1894, 2 Ch. 478) the same result was arrived at, although in giving judgment Lord Justice Davey said: 'No doubt in a sense the engineer will be the judge of his own conduct, and no doubt that is a position which *prima facie* raises some surprise in a judicial mind; but that is the contract of the parties.' As already indicated later decisions appear to have practically altered the law, although the judges always took care to say that *Ives* v. *Willans* is still good law. The result of the recent cases may be thus summarised. A contractor will not be bound to submit to the arbitrament of the employer's engineer (*a*) if the matter in issue is an unseemly personal dispute raising a vindictive feeling between the engineer and the contractor, and the engineer has so strongly expressed his view that it amounts to a prejudgment (*Nuttall* v. *Manchester Corporation* (1893) 8 T. L. R. 513); (*b*) if the nature of the dispute is such that the cross-examination of the engineer is essential (*Freeman* v. *Chester R. D. C.* (1911) 1 K.B. 783); (*c*) if the matter in issue is something outside the original agreement, e.g., a dispute as to whether the engineer and contractor had agreed to vary the original agreement (*Aird* v. *Bristol Corporation* (1913) A. C. 241); (*d*) if the conduct of the engineer himself is practically the only point in dispute (*Blackwell* v. *Derby Corporation* (1909) 75 J. P. 129). Finally, it was held in *Roberts* v. *Hickman* (1913) A. C. 229 that the grant of a certificate by an architect will not be a condition precedent to the builder's right to sue if, by writing letters to the employer, and allowing himself to be influenced by their views, the architect has disqualified himself from acting judicially although guilty of no fraud or improper conduct.

If the method of arbitration provided for in many existing forms of contract is declared to be impossible for any of the above reasons the only alternative is litigation, a method of settling disputes which employers, contractors, and engineers always seem to desire to avoid. What can be done to avoid such a calamity in relation to future contracts? The following courses are open. Insert a clause (*a*) referring all disputes to an arbitrator to be mutually agreed or to be nominated by the president of one of the Institutes (see, *e.g.*, the form approved by the Institution of Electrical Engineers, clause 47); or (*b*) referring disputes to a *named* arbitrator; or (*c*) refer disputes to the president of one of the Institutes whoever he may be. The first of these suggestions appears to offer the best practical solution of the difficulty. The writer, however, ventures to make the following suggestion which might possibly work in practice. Frame the arbitration clause so as to leave the decision of every question arising under the contract to the engineer but subject to a proviso that should it appear to the Court on an application to stay any action or proceeding brought in relation to the contract that the engineer is disqualified from acting as arbitrator the matters in dispute will be referred to an engineer to be agreed between

the parties, or failing agreement to be nominated by the president of the Institution of Civil Engineers. Another alternative is suggested by Mr. E. J. Rimmer in his Arbitration Clause in 'Engineering Contracts' (Constable & Co.). It is that a proviso should be added to the arbitration clause stating that if any action is brought the defendant may either (*a*) have the action stayed or (*b*) have the matter referred to an independent arbitrator appointed in one or other of the manners above suggested.

(10) THE ENGINEER AS ARBITRATOR.

(i.) **Generally.**—Engineers are frequently called upon to act as arbitrators to decide disputes of a technical nature wholly unconnected with any contract in which the engineer has been employed. Arbitrations are conducted in accordance with the provisions of the Arbitration Act 1883. An arbitrator may be appointed (*a*) by the Court; (*b*) by the terms of the contract itself or (*c*) by a person nominated for that purpose in the contract, e.g., the president of the Institution of Civil Engineers. As to appointment by the Court, this occasionally takes place when a prolonged scientific enquiry is necessary. A 'referee' of this kind may have power either to wholly dispose of the dispute or make an enquiry and report to the Court, in which latter case the Court itself gives the judgment after considering the report. As references of this kind are rare in practice they will not be further dealt with.

As a rule the engineer finds himself made arbitrator pursuant to the arbitration clause in an agreement. Any dispute arising under any contract may thus be referred, and the parties will as a general rule be bound to proceed to arbitration for the purpose of settling a dispute instead of bringing an action at law. Where a contract contains an arbitration clause, if one party commences an action, the other may apply to the Court to stay the action pending a reference and the action will generally be stayed, unless there is some good reason for not allowing the arbitration to proceed. For instance, a contractor alleged that he had been induced by fraudulent representations as to the nature of the soil to enter into a particular sewerage contract, and brought an action for fraudulent misrepresentation. It was held that such an action ought not to be sent to arbitration (*Monro* v. *Bognor Urban District Council* (1915) 84 L. J. K. B. 1091). But the Court will stay an action, and allow an arbitration to proceed, although the question at issue is one which might be more suitably tried in a court of law—*e.g.* the construction of a contract (*Metropolitan Tunnel, etc.*, v. *London Electric Ry.* (1926) 1 Ch. 371). (See also par. 9 (ix.), *supra*.)

(ii.) **Who may be Arbitrator.**—Any person upon whom the parties agree may act as arbitrator. Thus if in a contract with a local authority it is specified that the borough engineer shall be arbitrator there is no objection to his so acting, and the contractor can be compelled to accept his award (*Ives* v. *Willans*, *supra*, 2 Ch. 478). That is the broad rule, but the Court, as has been shown, always has power to refuse to enforce the arbitration clause in a case where it is obvious that the arbitrator ought not to act owing to bias, etc. Frequently the clause provides for the appointment of an arbitrator by each party with power to the arbitrators in case of differences to appoint an umpire. When this is done the umpire and arbitrators generally find it convenient to sit together to decide the case.

(iii.) **Proceedings before the Arbitrator.**—Witnesses must be sworn in the usual way. Due notice must be given to either party of the time when it is proposed to hold the sitting. In a case of great complexity it is well to have a preliminary sitting in order to require the parties to formulate the points in difference between them. By this means the issues may be considerably narrowed. The arbitrator should hear both sides, who may be represented by solicitor or counsel. He must never hold private communication with one party on the subject matter of the reference. He has no power to examine witnesses in the absence of the parties. An arbitrator who takes evidence in the absence of, and without notice to, a tenant, is guilty of legal misconduct, for which his award may be set aside (*In re O'Connor*, 88 L. J. K. B. 1242; *Ramsden* v. *Jacobs* (1922) 1 K.B. 640). It is for the arbitrator to decide every question whether of law or fact. He may, however, consult a solicitor or, for that matter, any other expert on legal points. Indeed the writer was recently concerned in a case in which, with the consent of the parties, the arbitrator had his solicitor sitting by his side. He should take full notes of the evidence, unless, as is frequently the case, the parties agree to have a shorthand note.

(iv.) **The Award.**—If the case is complex, the engineer is well advised to consult his solicitor as to the form of the award. The following are the features of a valid award, which should be in writing. (*a*) *It must not exceed the submission.* Thus if the question submitted was whether the stone used for building a dam was according to specification, the arbitrator would have no power to award that the stone used was better than as specified and that the employer must pay for it. (*b*) *It must extend to all matters in dispute.* If several distinct questions are referred and the arbitrator omits to decide upon any one of them, the whole award is bad. If in the case mentioned he were asked to decide (i.) was the stone as specified; (ii.) was it suitable for the purpose, he would have to decide both questions. (*c*) *It must be certain.* The award must be so framed that its meaning is clear to the parties; but according to a legal maxim, that is certain which is capable of being rendered certain. Thus to award that A. and B. shall pay a debt in the proportion in which A. and B. hold shares in a ship is a sufficiently definite award (*Watson* v. *Watson* (1671)

3ty. 28). (*d*) *It must be final.* The award must peremptorily state the arbitrator's finding. A mere expression of opinion that A. ought to pay B. such sum as C. thinks proper would not be a final award. Finally (*e*) *it must not be impossible, unreasonable, inconsistent,* or *illegal.* An award which directed that one party should do something illegal, *e.g.* trespass upon the land of another, would be invalid.

(v.) **Time for Making an Award.**—In the absence of agreement, an award must be made (*a*) within three months of the date of entering on the reference, or (*b*) within three months after having been called on to act by notice in writing from one of the parties, or (*c*) on or before any later day to which the arbitrator may by writing under his hand extend the time for making the award (Arbitration Act, 1889, Schedule 1 (c)). The power to extend the time is important in the case of a long and complicated reference, but it must be exercised within the period of three months above referred to. Unless the arbitrator extends the time, or the parties agree to allow him to do so, an application must be made to the Court to extend the time; and such an application may be made whether the time for making the award has expired or not (*ib.*, s. 9).

(vi.) **The Fees of an Arbitrator.**—The arbitrator should name his fee beforehand. It is best fixed at so much *per diem* for the hearing. If no preliminary arrangement is made, he is entitled to charge what is fair and reasonable, and he can keep back his award until the fees are paid (*Ponsford* v. *Swain*, J. & H. 433). When deciding in the award as to costs he should state who is to pay his fees; but he may insist upon their being paid by the party who takes up the award. He should not reveal his decision until after these formalities have been observed. Sometimes the *quantum* of an arbitrator's fees is left to the decision of a taxing master. On such a taxation, if the evidence goes to show that, in the opinion of persons in the same profession as the arbitrator, that his charges are fair and reasonable, the taxing master must allow them. In *Mason* v. *Lovatt* (1907, 23 T. L. R. 486) a quantity surveyor was allowed to charge 527*l.* 10*s.* for a reference which lasted 22 days, the arbitrator subsequently taking 13 days to consider his opinion. In *Llandrindod Wells Water Co.* v. *Hawksley* (1904, 20 T. L. R. 241) the fees of an umpire and two arbitrators all being engineers were allowed at 476*l.* 12*s.*, in respect of a reference which lasted 2 days. The arbitrator should state how his fees are made up.

(vii.) **Stating a Case for the Opinion of the Court.**—Where a specific question is referred to an arbitrator, and he decides it, the fact that his decision is erroneous in point of law does not make the award bad on its face so as to admit of its being set aside (*In re King and Duveen* (1913) 2 K. B. 32); nor will the mere fact that the dispute involves questions of law induce the Court to stay a reference to arbitration (*Rowe* v. *Crossley* (1913) 108 L. T. 11). But where a point of law arises during a reference, the arbitrator, if he does not care to decide it, may state a case for the opinion of the Court (Arbitration Act, 1889, s. 19), or the Court may compel him to state a case (*ib.*). He can also make his award in the form of a special case, leaving it to the Court to decide how the judgment shall be entered. Refusal to state a case may constitute misconduct on the part of an arbitrator (*Czarnikow* v. *Roth Schmidt & Co.* (1922) 38 T. L. R. 595).

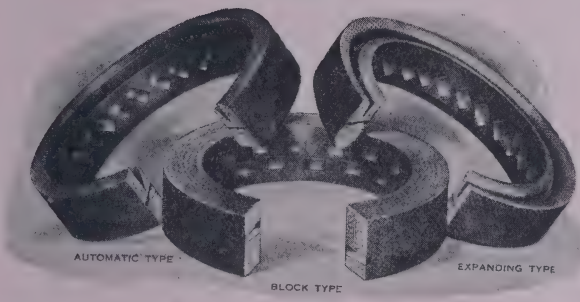
(viii.) **Costs of a Reference.**—On the question of costs, and as to the form of that part of his award which relates to costs, an arbitrator should consult his solicitor, because (*a*) highly technical questions arise with regard to costs and their taxation which no layman can be expected to understand, and (*b*) it is desirable that in this matter an arbitrator should observe as nearly as possible the principles which are recognised in courts of justice. Again, the defendant in the proceedings may have prepared a counter-claim in which he may have been successful wholly or in part. This further complicates the question of costs. It may be observed that there is no objection to an arbitrator employing a lawyer to advise him in the matter of costs or with reference to any other question which arises in a reference. In any event, and whether a solicitor is employed or not, the question of costs should be carefully considered, as the expenses of a reference are often wholly out of proportion to the sum in dispute. In litigation the general rule is 'costs follow the event'—an application of the maxim *vœ victis*. Unless the submission contains some special term as to costs, the arbitrator has full power to decide who is to pay them. He may award costs to be taxed 'as between solicitor and client'—which means that the successful party is nearly indemnified—or he may award costs to be taxed as between litigants in the ordinary way. He may also, in his discretion, award a fixed sum for costs (Arbitration Act, 1889, Schedule I. (i)), or he may declare that each party shall pay his own costs. In deciding whether to make a defendant pay costs, the arbitrator should (it is submitted) consider the nature of any offer made before the proceedings were commenced. Thus supposing a contractor claimed 5,000*l.* and the building owner made a firm offer of 4,000*l.* which was refused. After hearing the evidence, the arbitrator awards 4,000*l.* or less. In such a case he would be justified in disallowing the contractor any costs. An arbitrator can only make a successful plaintiff pay costs in exceptional circumstances as when (*e.g.*) it appears that although successful he should not have prosecuted his claim. It was held, however, in a case arising under the Small Holdings Act, 1908, the arbitrator in the exercise of his powers under that Act had wider powers in the matter of costs than a High Court judge (*Gray* v. *Baron Ashburton*, 115 L. T. R. 729).

(11) NOTES ON SALE AND PURCHASE OF MACHINERY.

The question which most frequently arises on the sale of machinery, motor cars, etc., is what is the warranty of fitness? Sometimes, of course, there is an express written warranty, but in the absence of that the matter is regulated by section 14 of the Sale of Goods Act, 1893, which provides (in effect) that there is no implied warranty or condition as to the quality or fitness for any particular purpose of goods supplied under a contract of sale, except (1) where the buyer expressly makes known the purpose for which the goods are required so as to show that the buyer relies on the seller's skill or judgment and the goods are of a description which it is in the course of the seller's business to supply (whether he be the manufacturer or not) there is an implied condition that the goods shall be reasonably fit for such purpose; provided that in the case of the sale of a specified article under its patent or other trade name, there is no implied condition as to its fitness for any particular purpose; (2) where the goods are bought by description from a seller who deals in goods of that description (whether he be the manufacturer or not) there is an implied condition that the goods shall be of merchantable quality; provided that if the buyer has examined the goods there shall be no implied condition as regards defects which such examination ought to have revealed; (3) an implied warranty or condition as to quality or fitness for a particular purpose may be annexed by the usage of trade; (4) an express warranty or condition does not negative a warranty or condition implied by the Sale of Goods Act unless inconsistent therewith. The result of these provisions is that in certain cases the vendor is made liable for latent defects, that is to say, for defects which would not be discoverable on an ordinary examination of the article. Sometimes a contract for the sale of machinery contains provisions for payment of the price by instalments after production of the certificate of the engineer that such instalments are due and payable. It was held in a Scotch case (*Howden* v. *Powell Duffryn Steam Coal Co.* (1912), S. C. 920, Ct. of Sess.) that where, in such circumstances, part of the machinery was rejected, but the manufacturers refused to accept the rejection, the production of the engineer's certificate was not a condition precedent to the right to recover payment.

In the case of an engine which is attached to the freehold, a question may arise, on a sale, as to when the property passes. In *Underwood Ltd.* v. *Burgh Castle Brick and Cement Syndicate* (1922, 1 K. B. 343), a horizontal condensing engine was sold at a price free on rail, London. It was bolted to and embedded in a flooring of concrete. Before it could be delivered on rail it had to be detached and dismantled. The sellers detached it, but in loading it on a truck they damaged it by accident so that the buyers refused to accept it. In an action by the sellers for goods bargained and sold it was held that the property in the engine had not passed to the buyers, inasmuch as the sellers had failed to do something necessary to put it in a deliverable state. Consequently the loss fell on the sellers and not on the buyers.

WALKER'S TRADE MARK LION PACKING



THE KING OF PACKINGS

A large firm in the U.S.A. writes "This only proves your Company's original contention that these metal pins lubricate the surfaces of the Pump plungers and keep them from scoring, thus preserving the packing and increasing its life."

Curve, logarithmic, 43
Curves, 39
——— canal, 1586
——— cycloidal, 27, 39, 40
——— differential coefficients of, 16
——— gaseous fuel, 1602
——— of displacement of ships, 2343
——— polar (light), 2524
———, radii of, table of, 662
——— railway, 655, 656, 659
——— crossing, 658
——— ranging, 659
——— resistance of, 680
——— setting out by offsets, 666
——— superelevation of outer rail fo 6
——— tables for calculating, 651
——— transition, 664
——— vertical, 666
Cutter dredgers, suction, 1545
Cutters, coal, 2581
———, the 'Hardiax,' 2582
——— milling, 1098
——— speed of, 1098
——— pitch of teeth of, 1100
——— tube, 1163
——— wood, sharpening angles of, 1146
Cutting edges of drills, 1107
———, electric, 2778
——— lubricants, 1152
——— machines, metal, 1093

CUT

Cutting, oxy-acetylene, 2764
—— - plates, power required for, 1135
—— speeds of lathe tools, 1146
—— - tools, angles of, 1145
—— —— tempering, 1137, 1140, 1144
Cuttings, railway, walls for, 616
—— to determine volume of earth in, 585
Cyanogen, 2465
Cycle engineers' screw threads, 1215
Cyclic variation recorder, Mirrlees, 1954
Cycloid, 27, 39, 40
——, to construct, 27
Cycloidal curves, 37, 39, 40
—— teeth, 1013
Cyclostyle, 204
Cylinder area ratios (marine engines), 2360
—— bridge piers, 355
—— diameter (marine engines), calculation of, 2362
—— ratios, 1791
—— —— of marine engines, 2360
—— sinking by pneumatic process, 606
Cylinders, allowable pressure in, 302
—— engine, 687, 2292
——, for foundations, 606
—— hydraulic, thickness of, 1306, 1308
—— —— strength of, 1308
—— of compound and simple locomotives of equivalent power, 687
—— —— locomotives, 687
—— —— gas and oil engines, lubrication of, 1065
—— —— hydrostatic presses, thickness of metal of, 1411
—— —— locomotives, 687
—— —— marine engines, 2360, 2362
—— —— steam engines, 1794
——, sinking, by pneumatic process, 606
—— locomotive, 2 and 4, relative areas of, [687
—— ram, 1411
—— thick, allowable pressure in, 302
Cylindrical iron boilers, marine, length of, 2386
—— —— —— ——, diameter of tubes of, 2386
—— sewers, brickwork for, 1470
—— valves for locomotives, 688

DIA

Dams, rock-fill, 1354
—— shrinkage of, 1460
—— spillway, 1357
—— stability of, 1356
—— timber, 1354
—— water losses through, 1452
Danish regulations for working lifts, 1416
Danube river training works, 1571
D.A.V. gas engine, Crossley's, 1923
Davey-Paxman (*see* Paxman)
Dawson, J. & Son's 'Lincona' Balata V Belt Drive, 979
—— Philip, tensile strength of copper, 283
Day, C., on tar fuel for Diesel engines, 2144
Daylight, artificial, 2543
Daysohm's electric welding system, 2771
D.B. patent conveyors, 945
Deacon water meter, 1500
Dead-weight of ships, 2351
Deals, standards of, 458
De-aerater, Allen, 1699
—— Kestner, 1699
—— Weir, 1700
Decimal equivalent of fractions, 121
Decimals of a £, to reduce shillings to, 124
Decomposition of light in the spectrum, 230
Deep mine shafts, 2580
—— wells, water-raising from, by compressed [air, 1339
Deflection of beams, 325, 417, 565
Degassing plant, 1698
Degree, length of, in latitude and longitude, 185
Degrees of temperature, conversion of, 209
—— —— —— value of, 213
Deighton furnaces, 1600
Delta metal, 280, 281, 284, 1040, 2436, 2439, 2715, 2721, 2726, 2728, 2734
—— —— corrosion of, 284
Demagnetisers, 1127
Density, change of, by heat, 227
Depositing floating dock, 1539
Depreciation of plant and machinery, 2887
Depth of keystones for arches, 626
Derbyshire iron, 2678
Derrick cranes, 908
Design of ball bearings for big loads, 1040
—— - engines, 1790
—— locomotives, 675
—— - reinforced concrete structures, 555
Designs, registration of, 2831
Despatch tubes, pneumatic, 1266
Destructors, refuse, 2133
—— —— —— Heenan, 2133
—— —— —— Pontypridd, 2133
—— —— —— Rotterdam, 2134
De-Superheaters, 1683
Detectors, earth, 2233
Detonators, 2571, 2784
Development of water-power, 1345
Dewar, greatest artificial cold produced by, 211
Dexine sheets, steam joints, 1744
—— - pump valves, 1328
Dexonite, 2334
Diagram factor (steam indicator), 2361
—— of steam indicator, to interpret, 1774
Dial, cranked gimbal, Stanley's, 178
Dials, clock, size of, 2801
Diameter of axles, 1077
—— - crank pins, 1077
—— - marine engine cylinders, 2362

D.A. (acetylene), 788, 1553, 1559, 2159, 2480, 2480, 2751
—— —— rail welding, 788
Daimler motor-car engines, 1987
Dam, Assuan, 1477
—— - Croton, 1475
—— - Vyrnwy, 1474
Damp course of walls, 470
—— -proofing, 'Callendrite,' 470, 1474
Dampness in walls, to remedy, 509, 2790
Dams, 1354, 1473
—— balk, 613
—— basic economy of, 1458
—— coffer, or puddle, 611
—— design of, 1356
—— François cementation process for, 1474
—— earth, 1354, 1473
—— masonry, 1354, 1473
—— Molesworth's rules for, 1473
—— puddle, 611
—— Rankine's rule for, 1473
—— reinforced concrete, 1354

DIA

Diameter of rivet holes, 329
——— shafting, 1078, 1079
——— steam main for heating, 2489
——— tubes of cylindrical marine boilers,
——— wheels, 1006 [2386
Diamond mesh expanded metal, 436

PIP

Pipes, brass, weight of, 257 [2493
—— British standard low-pressure heating,
—— cast-iron, 256, 258, 276, 1492, 2473
———— , weight of, 256, 258, 1492, 2493
—— concrete, 442, 570, 1365, 1425
———— lined, 1311
—— copper, weight of, 257, 267
—— design of, 1364
—— diameter of, 1481
—— discharge of water through, 1360, 1426, 1481, 1485, 1490, 1491
—— drain, 531, 1441, 1493
—— exhaust, 1743
—— expanded steel concrete, 442
—— flanges of, 1232
—— flow of air through, 1156
———— steam through, 1745
———— water through, 1360, 1426, 1481, 1485, 1490, 1491
—— for waterworks, 1481
——, gas, 256, 2473
—— ——, British standard, 276
———— threads of, 1218
———— weight of, 256, 2473
—— heating, 2489
—— hydraulic, thickness of, 1306
—— iron, corrosion of, 1481
—— —— soil, weight of, 1443
—— —— water and hydraulic, thickness of,
—— lead, corrosion of, 521, 1481 [1308
———— soil, 1443
————, strength of, 302
———— weight of, 257, 1443, 1493
—— pressure in, 1306, 1364
—— rain-water, 521
—— reinforced concrete, 570, 1365
—— salt glazed, for sewers, 532, 1423
—— screw threads of, 1216
—— sewer, British standard, 1423
—— socket, and fittings, 276
—— soil, 1443
—— speed of water through, 1306, 1487
—— steam, 1739
—— ———— bends, 1739
———— —— copper, 1740
———— —— corrugated, 1740
———— —— coverings of, 1749
———— —— exhaust, 1743
———— —— flow of steam through, 1747
———— —— joints of, 1743
———— —— leaks in, 1744
———— —— Lloyd's rules for, 1741
———— —— loss of heat from, 1747
———— —— of boilers, 1739
———— —— pressure, drop in, 1745
———— —— size of, 1744
———— —— steel bends, 1739
———— —— thickness of, 1741
———— —— valves of, 1726
———— —— weight of, 256, 261
—— steel, corrosion of, 1481
————, design of, 1364
————, identification of, 278
—— thicknesses of, 275, 1306
—— velocity of water in, 1306, 1360, 1426 1481, 1485, 1489, 1491
—— water, 256, 278, 1481
———— —— British standard, 276
———— —— corrosion of, 521, 1481

PIP

Pipes, water hammer in, 1409
——————, incrustation of, 1481
——————— joints in, 1308
——————— threads of, 1216
——————— weight of, 256
——————— wooden stave, 1364
——— wrought-iron, 256, 2473
——————————— weight of, 256, 2473
Piping for cold-storage rooms, 1283
Piston of steam indicator, 1771
——— nut-lock plate, 1810
——— packing-rings, metal for, 2730
——————————— Rowan, 1809
Piston rod packing rings, Beldam (Beldam Packing & Rubber Co.) 1807, 1808

WALKER'S LION PACKING TRADE MARK

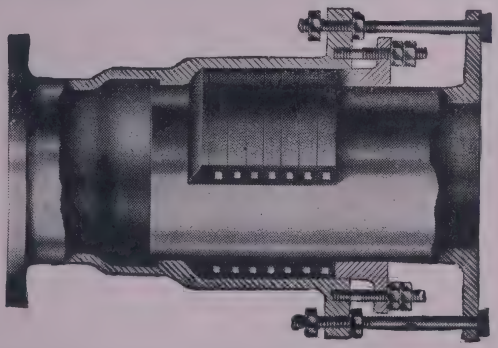
PATENT
'FLEXMET' PACKING

As its name implies, this is an exceedingly Flexible Semi-Metallic Packing. It has a continuous anti-friction metal wearing face.

Suitable for Shallow Stuffing Boxes and Rotary Engines.

'EMERALD' EXPANSION GLAND PACKING

RESILIENT



DURABLE

A positive cure for one of the most troublesome joints with which Engineers have to contend.

JAMES WALKER & CO. LTD.

'LION' WORKS, WOKING, Surrey
(late of LION WORKS, LONDON, E.14)

Telephone : Woking 1040.
Write for Catalogue No. 91.

Telegrams : 'Lioncelle, Woking.'
See also beginning of Index.

(To face end of Index, p. 2976)

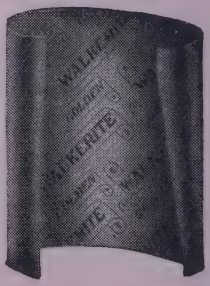
WALKER'S TRADE MARK LION PACKING

'GOLDEN WALKERITE'

COMPRESSED ASBESTOS FIBRE JOINTING

Has proved by Practical Experience to be the Best Jointing on the Market.

SUITABLE FOR STEAM, WATER, PETROL, ACID, AMMONIA, OIL, ETC.



SUPPLIED IN SHEETS, 36″×60″ 40″×40″ 48″×48″ 54″×63″ from $\frac{1}{64}$″ thick.

JOINTS CUT TO ANY SHAPE OR SIZE.

GENUINE BRITISH MANUFACTURE

SOLE MANUFACTURERS:—

JAMES WALKER & CO. LTD.

'Lion' Works, Woking, Surrey

(late of LION WORKS, LONDON, E.14.)

The No. 618 Avery Universal Testing Machine

AVERY

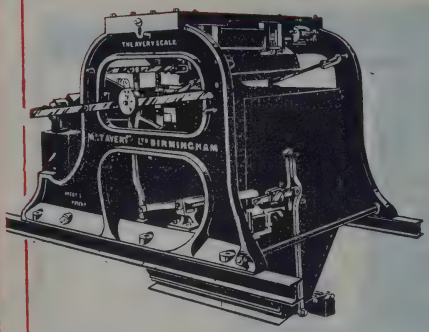
This machine is of the vertical type, and is "Universal" in character, permitting different forms of test to be made without change of tools.

It is designed upon the single-lever principle, the load upon the test piece being indicated by a poise weight traversing a graduated scale upon the steelyard.

The steelyard is graduated from zero to 50 tons, the finest subdivisions being .01 ton. Makers of the World's largest Testing Machines.

Write for list No. 827.

W&T.AVERY LTD
SOHO FOUNDRY BIRMINGHAM



The No. 48 Avery Patent Automatic Coal Weigher.

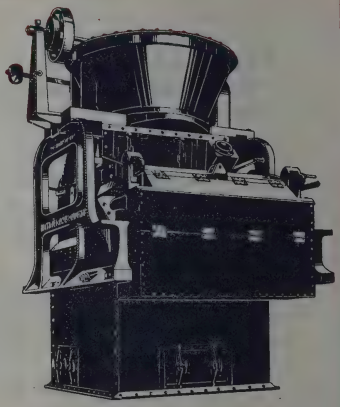
Is the embodiment of reliability, accuracy and efficiency, and specially designed to check accurately coal intake and consumption, with reduced labour costs.

Write for list No. 839 to Automatic Dept.

AVERY

ACCURATE.
RELIABLE.

This automatic weigher gives accurate records of pulverized fuel consumption without dust escape. Machine illustrated weighs 50 tons per hour from an overhead storage hopper, delivers to the pump, and automatically keeps an accurate record of all fuel consumed.



The No. 52 Avery Patent Dustproof Automatic Weigher for Pulverized Coal.

W&T.AVERY LTD
SOHO FOUNDRY BIRMINGHAM

A1557

'THE ENGINEER'S YEAR-BOOK' CLASSIFIED DIRECTORY OF LEADING ENGINEERING AND ALLIED FIRMS ADVERTISING IN THE 1928 EDITION.

A RELIABLE GUIDE FOR THE USE OF BUYERS OF ENGINEERING MATERIALS, MACHINERY, TOOLS, PLANT, APPLIANCES, ETC.

For Advertisers' Addresses, and Positions of their Announcements in the 'Year-Book,' consult foregoing Alphabetical List, pages 2977 to 2990

The aim of the Proprietors of 'The Engineer's Year-Book' is to include in this publication only the most reputable firms' announcements, so that readers desiring to order, or specify, the various specialities advertised, may do so with confidence.

***** French, Italian, Spanish, and Russian translations of the terms used in this Directory are given on pages 3059 to 3144.**

RÉPERTOIRE ANALYTIQUE DES ANNONCEURS POUR 1928.

Guide pratique des acheteurs de matériaux pour constructions mécaniques, de machines, d'outils, outillages, appareils, etc.

Les propriétaires de 'The Engineer's Year-Book' (L'Annuaire de l'Ingénieur) se sont efforcés de ne faire figurer dans la présente publication que les annonces des maisons les mieux réputées ; les lecteurs désireux de commander ou de spécifier les différentes spécialités annoncées peuvent donc le faire en toute confiance.

On trouvera pages 3059–3078 la liste des équivalents de ces termes en Français.

Pour les adresses des Annonceurs et les renvois à leurs annonces dans l'Annuaire, voir l'Index alphabétique ci-dessus, pages 2977–2990.

GUIDA CLASSIFICATA DELLE DITTE DI MAGGIOR IMPORTANZA CHE HANNO DEGLI ANNUNCI NELL' EDIZIONE DEL 1928.

Ai compratori di materiale per la meccanica, e di macchinario in genere, questa Guida è assai utile.

I proprietari della 'Engineer's Year-Book' (l' Annuario dell' Ingegnere) si sono limitati a pubblicare in questa guida solo i nomi delle case più rinomate; i lettori che desiderano ordinare o specificare specialità comprese in questi annunci lo possono quindi fare con tutta sicurezza.

A pagine 3079–3098 trovasi la traduzione in italiano dei termini usati in questo elenco.

Per gli indirizzi delle ditte aventi degli annunci ed il posto dove detti annunci appaiono nella guida vedesi l' elenco alfabetico a pagine 2977–2990.

GUÍA CLASIFICADA DE ANUNCIADORES PARA 1928

Esta Guía es muy conveniente para los compradores de materiales de ingeniería, maquinaria, herramientas, instalaciones, utensilios, etc.

La aspiración de los propietarios de 'The Engineer's Year-Book' ('El Anuario del Ingeniero') es incluir en esta publicación solamente los anuncios de las casas de la mejor reputación ; así es que los lectores que deseen pedir ó especificar cualquiera de los diversos artículos anunciados pueden hacerlo así con confianza.

Una traducción de los términos equivalentes en Castellano se hallará en la lista, páginas 3099–3120.

Para señas de anunciadores y referencias á sus anuncios, consúltese la precedente Lista alfabética, paginas 2977–2990.

ПОДРОБНЫЙ УКАЗАТЕЛЬ СПЕЦІАЛЬНОСТЕЙ АНОНСОДАТЕЛЕЙ 1928 г.

Удобное Руководство для Покупателей Инженерныхъ матеріаловъ, инструментовъ, машинъ, приспособленій, принадлежностей и пр. и пр.

Редакція 'The Engineer's Year-Book' (Инжечерный Ежегодникъ) въ настоящемъ изданіи включила объявленія лишь первоклассныхъ фирмъ, такъ что читатель можетъ съ полной увѣренностью снестись съ любой изъ этихъ фирмъ или помѣстить свои заказы на любыя изъ указанныхъ спеціальностей.

Переводъ терминовъ данъ также на Французскомъ и Италіянскомъ и Испанскомъ Русскомъ языкахъ—см. стр. 3121–3144.

Адреса фирмъ и свѣдѣнія объ ихъ спеціальностяхъ въ 'The Engineer's Year-Book' (Инженерный Ежегодникъ)—см. предыдущій алфавитный списокъ—стр. 2977–2990.

D	
Dalles et planches en ciment	Cement Slates and Boards
Découpage et soudure autogène des métaux	Metal Cutting and Welding
Démagnétiseurs	Demagnetizers
Démarreurs à liquide et combinateurs	Liquid Starters and Controllers
Désincrustants pour chaudières	Boiler Discrustants
Destructeurs (Séparateurs magnétiques pour)	Destructors (Magnetic Separators for)
Destructeurs de déchets	Destructors (Refuse)
Désurchauffeurs de vapeur	Steam De-Superheaters
Détrempe	Distemper
'DEXINE' (pour vapeur H.P., garnitures acides et hydrauliques)	'DEXINE' (for H.P. Steam, Acid and Hydraulic Packings)
'DEXONITE' (superébonite, pour acides et alcalis; garnitures, et pour isolation électrique)	'DEXONITE (Super Ebonite, for Acids and Alkalies; fittings, and Electrical insulation material)
'Duralumin' 'Vickers'	'Duralumin' 'Vickers'
Dynamite	Dynamite
Dynamomètres	Dynamometers
Dynamos et moteurs	Dynamos and Motors
E	
Eau d'alimentation des chaudières (Élimination de l'huile de l')	Boiler Feed-Water, Oil Elimination from
Ébonite	Ebonite
Éclairage des trains	Lighting (Train)
Éclairage des usines	Factories (Lighting of)
Éclairage et chauffage (Installations de gaz acétylène pour)	Lighting and Heating (Acetylene Gas Plants for)
Écoles et collèges de mécanique	Schools and Colleges (Engineering)
Économiseurs de combustible	Fuel Economisers. *See* Economisers
Écrous	Nuts
Électriques (Instruments et appareils)	Electrical Instruments and Apparatus. *See* Instruments and Apparatus (Electrical)
Électro-aimants de levage	Lifting Magnets
Électrodes (pour la soudure à l'arc électrique)	Electrodes (for Electric Arc Welding
Éléments et batteries d'accumulateurs électriques. *Voir* Accumulateurs électriques	Electrical Storage Cells and Batteries. *See* Storage Cells
Élévateurs. *Voir* Levage et halage	Elevators. *See* Lifting and Hoisting
Éliminateurs d'huile	Oil Eliminators
Émaux, couleurs et vernis	Enamels, Colours, and Varnishes
Embrayages	Clutches
Embrayages à frottement	Friction Clutches
Enduits imperméabilisants	Waterproofing Compounds
Enduits pour parties brillantes	Bright Part Coatings
Enduits pour parties brillantes et apprêts pour machines	Coatings (Bright Part) and Machinery Finishes
'Endural' Câbles électriques	'Endural' Electric Cables
Engrenages	Gearing
Engrenages, arbres de transmission, etc., pour usines. *Voir* Arbres de transmission et engrenages	Mill Gearing, Shafting, etc. *See* Shafting and Gearing
Engrenages cylindriques et coniques	Spur and Bevel Gearing
Engrenages de réduction	Reduction Gears

Pour les noms des fabricants des spécialités ci-dessus, se reporter aux rubriques correspondantes en anglais dans le 'Classified Directory and Buyers' Guide' ('Répertoire Analytique des Annonceurs'), pages 2993–3056.

Revêtements pour chaudières et tuyaux	Boiler and Pipe Coverings
Revêtements pour murs et plafonds	Wall and Ceiling Sheets
Revêtements pour tuyaux	Pipe Coverings
Riblons de fer et d'acier	Iron and Steel Scrap
Rivets en fer, acier, cuivre, bronze de marine, etc.	Rivets (Iron, Steel, Copper, Naval Brass, etc.)
Riveuses électriques	Riveters (Electric)
Riveuses hydrauliques et pneumatiques	Riveters (Hydraulic and Pneumatic)
Robinets en cuivre pour eau, vapeur et gaz	Cocks (Brass) for Water, Steam, and Gas
Rodeurs de sièges de soupapes	Valve Reseaters
Rondelles pour verres d'indicateurs de niveau	Gauge Glass Washers
'Rosseline' (pour moteurs à gaz et à pétrole)	'Rosseline' (for Gas and Oil Engines)
Roues à empreintes pour chaînes	Chain Wheels
Roues d'engrenage	Wheel Gearing
Roues, moteurs et turbines hydrauliques	Water Wheels, Water Motors, and Turbines
Roues Pelton	Pelton Wheels
Rouleaux en acier	Steel Rollers
Routes bétonnées (Entrepreneurs de construction de)	Concrete Roads (Contractors for)

S

Sabots de freins	Brake Blocks
Scies pour bois et métaux	Saws for Wood and Metal Cutting
Séchage du bois de construction	Timber Seasoning
Sécheurs et épurateurs de vapeur	Steam Dryers and Purifiers
Sections refoulées brevetées en laiton, bronze, etc.	Sections (Patent Extruded), Brass, Bronze, etc.
Segments de pistons	Piston Rings
Séparateurs d'eau de condensation	Steam Separators
Séparateurs de graisse	Grease Separators
Séparateurs de suie	Soot Removers
Séparateurs électromagnétiques	Separators(Magnetic)
Séparateurs magnétiques	Magnetic Separators
Séparateurs mécaniques	Mechanical Separators

Rampas de ferrocarriles	Railway Ramps
Recalentadores	Superheaters
Recalentadores de Locomotoras	Locomotive Superheaters
Recalentadores Marinos	Marine Superheaters
Recipientes de almacenaje (para muebles de acero)	Storage Bins (for Steel Furniture)

Para hallar los nombres de los fabricantes de los artículos especiales antes mencionados, refiéranse á los títulos equivalentes en inglés en la Classified Directory and Buyers' Guide ('Guía Clasificada de Anuncios'), páginas 2993–3056.

ESPAÑOL.	INGLÉS.
Recortes y Desperdicios de Metales	Metals (Scrap)
Redes de Alambre Galvanizado	Galvanised Wire Netting
Refrenadores y Aparatos de Arrancada (Líquido)	Controllers and Liquid Starters
Refrigeradores de Aceite	Oil Coolers
Refuerzos de Embragues	Clutch Linings
Refuerzos de Frenos y Embragues	Brake and Clutch Linings
Refuerzos para Hormigón Armado	Concrete (Reinforcement for)
Registradores de Agua	Water Recorders
Registradores de CO_2	CO_2 Recorders
Registradores de Gastos y Tiempo	Costs and Time Recorders
Registradores de la Producción de Cada Máquina	Machine Output Recorders
Registradores de Tiempo	Time Recorders
Reguladores Automáticos	Regulators (Automatic)
Reguladores de Agua de Alimentación	Water Regulators (Feed)
Reguladores de Temperatura	Temperature Regulators
Reguladores de Máquinas de Vapor	Governors (Steam Engine)
Reguladores Hidráulicos	Governors (Hydraulic)
Registradores de Velocidad	Recorders (Speed)
Relojes Eléctricos	Electric Clocks
Remachadoras Eléctricas	Riveters (Electric)
Remachadoras Hidráulicas y Neumáticas	Riveters (Hydraulic and Pneumatic)
Remaches de Hierro, Acero, Cobre, Bronce Naval etca.	Rivets (Iron, Steel, Copper, Naval Brass, etc.)
Removedores de Hollín	Soot Removers
Reparación de Buques y de Máquinas Motrices	Ship and Engine Repairers
Retortas de Gas	Gas Retorts
Rieles Fabricantes de	Rail Manufacturers
Rieles y Accesorios de Acero	Steel Rails and Accessories
Rieles y clavazón	Rails and Fastenings
Rociadoras	Spraying Machines
Rodillos de acero	Steel Rollers
'Rosseline' (para Máquinas de Gas de Petróleo)	'Rosseline' (for Gas and Oil Engines)
'Ruberoid,' Material para Tejados	'Ruberoid' Roofing
Ruedas de engrane de cadenas	Chain Wheels
Ruedas de Pelton	Pelton Wheels
Ruedas Hidráulicas, Motores Hidráulicos y Turbinas	Water Wheels, Water Motors, and Turbines
S	
Secaderos y Purificadores de Vapor	Steam Dryers and Purifiers
Secciones de (Metales Exturbados, con Privilegio de Invención) Bronce, Latón, etca.	Sections (Patent Extruded), Brass, Bronze, etc.
Señales. *Véase* Señales de Ferrocarriles	Signals. *See* Railway Signals
Señales de Ferrocarriles y Utensilios de Seguridad	Railway Signals and Safety Appliances
Señales Impermeables Herméticas para Minas	Mining Signals (Water-tight)
Separación de Aceite del Vapor Condensado	Separation of Oil from Condensed Steam
Separadores de Grasa	Grease Separators
Separadores de vapor	Steam Separators
Separadores Magnéticos	Magnetic Separators

Para hallar los nombres de los fabricantes de los artículos especiales antes mencionados, refiéranse á los títulos equivalentes en inglés en la Classified Directory and Buyers' Guide ('Guía Clasificada de Anuncios'), páginas 2993–3056.

ESPAÑOL.	INGLÉS.
Separadores Magnéticos para Destructores	Destructors(Magnetic Separators for)
Separadores mecánicos	Mechanical Separators
Serpentinas	Pipe Coils
Sextantes	Sextants
Sierras para cortar madera y metales	Saws for Wood and Metal Cutting
Sistemas de Alambres Eléctricos Flexibles	Wiring Systems (Flexible)
Sistemas de Instalación de Alambres eléctricos. *Véase* Sistemas de instalación de Alambres Flexibles)	Electric Wiring Systems. *See* Wiring Systems (Flexible)
Sistemas para conducir dinero	Cash Carrier Systems
Soldadura	Solder
Soldadura á Martillo y Corte de Metales	Welding and Cutting of Metals
Soldadura 'Daysohms' de Arco Eléctrico	'Davsohms' Electric Arc Welding
Soldadura de Arco Eléctrico para Reparar Calderas	Boiler Repairs (Electric Arc Welding for)
Soldadura de Oxiacetileno	Oxy-AcetyleneWelding
Soldadura Eléctrica	Electric Welding
Soldadura 'Thermit'	'Thermit' Welding
Soportes de rodillos	Roller Bearings
Sopletes de Acetileno para Solda y Cortar	Blowpipes (Acetylene Welding & Cutting)
Sopladores. *Véase* Aparatos Soplantes	Blowers. *See* Fans
Suelos, etca. (Resistentes al Fuego)	Floors, etc. (Fire Resisting)
Sujetadores ('Jubilee' con movimiento de rosca (Patente))	Clips ('Jubilee' Worm - Drive (Patent))
Sujetadores de expansión	Expanding Clips
Sujetadores de mangueras	Hose Pipe Clips
Sujetadores de radiadores	Radiator Clips
Superficies de Fricción	Friction Surfaces
Superficies de Fricción de 'Ferodo'	'Ferodo' Friction Surfaces

T

Tableros de conmutadores de batería	Battery Switchboards
Tableros de conmutadores de baterías de acumulación	Storage Battery Switchboards
Tachones, Pernos y Tuercas de Aluminio	Aluminium Studs, Bolts and Nuts
Tachos al Vacío (Concentradores)	Vacuum Pans (Concentrating)
Tachos y Pailas para Azucar y otras Industrias	Evaporators for Sugar and Trade Liquors
Taladros de Punta de Diamante	Diamond Drillers
Taladros para Perforar Rocas	Rock Drills
Taladros Salomónicos	Twist Drills
Taladros y Cinceles para Minas de Carbón	Coal Drills and Cutters
Taladros y Máquinas para Taladrar	Drills and Drilling Machines
Taladros y Martinetes Portátiles Eléctricos	Electric Portable Drills and Hammers
Tambores para Aceite	Oil Drums
Tanques y Cisternas	Tanks and Cisterns
Taquímetros	Tachometers
Tejados, Edificios de Hierro, etca.	Roofs, Iron Buildings, etc.
Tejidos de Fricción 'CHEKKO'	'CHEKKO' Friction Fabrics
Tejas de Amianto	Asbestos Roofing Tiles
Tejas y Hojas acanaladas (Amianto-Cemento)	Corrugated Tiles and Sheets (Asbestos-Cement)
Tela metálica	Wire Gauze
Temple superficial	Case Hardening
Termómetros	Thermometers

The more searching the test, the more certain is the adoption of

LEYLAND RUBBER

MANUFACTURES

Rubber Belting

for driving and conveying purposes.

Rubber Hose,

manufactured by the moulded and braided process, in continuous lengths up to 500 ft.

Rockdrill Hose,

for use with all classes of machinery worked by compressed air.

Petrolic Hose,

built and proofed to withstand the action of petrol, spirit, petroleum, and heavy oils.

Mechanical Rubber Goods and Engine Packings,

of every description.

Prices and lists supplied on application.

The LEYLAND & BIRMINGHAM RUBBER Co. Ltd.

Head Office: LEYLAND, NEAR PRESTON, LANCS.

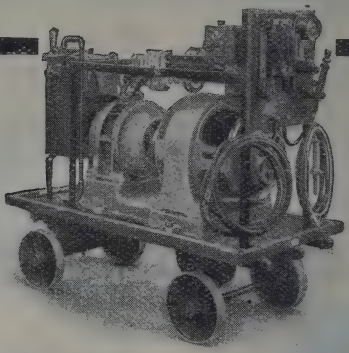
Works: LEYLAND, GLASGOW, MITCHAM, AND PRESTON.

Branches:

London, Birmingham, Manchester, Cardiff, Glasgow, Newcastle-on-Tyne, Dublin, Leeds, Liverpool, Preston, Johannesburg, Calcutta, and Buenos Aires.

Distributing Agents throughout the World.

Ten types of Plant



Ten grades of Electrodes

WILSON PLASTIC-ARC ELECTRIC WELDING PLANTS

and

"Colour-tipt" WELDING METALS

are indispensable to the making of

A PERFECT WELD

Have you tried GRAPHOL—a penetrating lubricant and mined graphite conveyor? It will lubricate under all conditions, and surfaces seized up by rust can be freed instantly.

ENGINEERING TRAINING

Imperial College of Science and Technology.

VISITOR—H.M. THE KING.

CITY & GUILDS (ENGINEERING) COLLEGE,

Exhibition Road, South Kensington, London, S.W. 7.

The City and Guilds (Engineering) College, the Engineering Section of the Imperial College, provides complete Courses of Instruction leading up to, and including, the highest specialised instruction to fit Students to take leading positions in the industrial world as Civil, Mechanical or Electrical Engineers, Scientific Advisers, Investigators or Experts in the Engineering industries. The College also provides opportunities for those already qualified who desire to take up more advanced courses of training and research in branches of Engineering in which they are specially interested.

The Departments of the College are as follows :—

ENGINEERING, MECHANICAL AND MOTIVE POWER—
Under the direction of Prof. Dalby, F.R.S., M.Inst.C.E.

ENGINEERING, CIVIL, AND SURVEYING—
Under the direction of Prof. Dixon, M.Inst.C.E.

ENGINEERING, ELECTRICAL—
Under the direction of Prof. Fortescue, M.I.E.E.

MATHEMATICS—
Under the direction of Prof. Chapman, F.R.S.

The following Diplomas are awarded to Students who satisfactorily complete a full Course of from two to four years :—

The Associateship of the City and Guilds of London Institute (A.C.G.I.).

For admission to the courses qualifying for this Diploma candidates are required to pass one of the Entrance or Matriculation Examinations of the College held in April and September (application to be made not later than the first Friday in April or the first Monday in September respectively); or to have passed the Matriculation of the University of London in certain subjects.

B.Sc. in Engineering of University of London.

Students who enter by the Matriculation Examination of the University of London are eligible for the B.Sc. in Engineering of the University through the College Examinations alone.

The Diploma of the Imperial College (D.I.C.).

(For advanced specialised or fourth-year work.)

Further information and the Prospectus of the College may be obtained on application to the Registrar.

LONDON

ENGINEERING TRAINING

UNIVERSITY OF LONDON
KING'S COLLEGE

FACULTY OF ENGINEERING

Complete courses of study, extending over three years, are arranged in :—

CIVIL, MECHANICAL AND ELECTRICAL ENGINEERING

for the Engineering Degrees of the University of London, and for the Diploma and Certificate of the College.

SENIOR STAFF

Professor G. COOK, D.Sc., M.I.Mech.E., A.M.Inst.C.E. Mechanical Engineering. (Dean.)
S. J. DAVIES, M.Sc., M.I.Mech.E., Reader in Mechanical Engineering.
Professor A. H. JAMESON, M.Sc., M.Inst.C.E. Civil Engineering.
C. H. LOBBAN, D.Sc., A.M.Inst.C.E. Reader in Civil Engineering.
Professor E. WILSON, M.Inst.C.E., M.I.E.E. Electrical Engineering.
F. S. ROBERTSON, M.I.E.E. Lecturer.
Professor S. A. F. WHITE, M.A. } Mathematics.
Professor A. E. JOLLIFFE, M.A. }

Considerable Extensions have been made in the Engineering Department. These include a large additional drawing-office, lecture room, and laboratory for Hydraulics and Strength of Materials in the Civil and Mechanical Departments, and research rooms, including Wireless Telegraphy, in the Electrical Engineering Department. Large additions have been made to the equipment of the Laboratories in the three Departments for purposes of teaching and research.

There is a College Hostel and a large Athletic Ground.

For full information apply to

The SECRETARY, King's College, Strand, W.C.2.

President - - - THE HON. SIR CHARLES PARSONS, K.C.B., M.A., LL.D., D.Sc., F.R.S.

Head of School - - ALEX. R. HORNE, O.B.E., B.Sc. (LOND.), F.R.S., (EDIN.), M.I.Mech.E., Assoc. M.Inst.C.E.

Head of Electrical Engineering Dept. - PHILIP KEMP, M.Sc.Tech., M.I.E.E., Assoc. A.I.E.E.

Day Courses.

Courses extending over three years are offered in Mechanical, Structural, Electrical and Motor Engineering, Each Course embraces lectures, laboratory, and workshop drawing-office practice.

The Courses in Mechanical and Electrical Engineering are recognised by the Institutions of Mechanical and Electrical Engineers respectively and the Board of Education for the award of Senior and Advanced National Diplomas.

School Diplomas are awarded in all branches.

Entrance Examinations are held in July and September.

Evening Classes.

Courses of Study are offered in Civil, Mechanical, Electrical, Motor and Gas Engineering. These are designed to afford a thorough training, of an advanced standard, in the science and practice of Engineering. The work undertaken covers the requirements of the examinations for admission to the several Engineering Institutions.

The Courses in Mechanical and Electrical Engineering are recognised for the award of National Certificates.

Prospectuses, and full particulars, may be obtained from the Director of Education, The Polytechnic, 309 Regent Street, W. 1.

LONDON

ENGINEERING TRAINING

The Crystal Palace School of Practical Engineering

Founded 1872.

Mechanical and Civil Divisions.

President: J. W. WILSON, M.Inst.C.E., M.Inst.Mech.E., F.S.E.
Principal: MAURICE WILSON, M.Inst.C.E., Past President, Society of Engineers. *Vice-Principal:* F. C. P. LAWRENCE, M.S.E., A.M.Inst.Struct.E.

ASSISTED BY A STAFF OF LECTURERS AND INSTRUCTORS.

The School may be Inspected on application to the Principal, from whom all further information may be obtained.

This School was established for the purpose of providing Students of any branch of Engineering with thorough practical and theoretical instruction in the rudiments of the profession and in the manipulation of materials. The institution has since been largely extended.

The School is approved by the Council of the Institution of Civil Engineers' and Students who pass through its complete course and otherwise comply with the current regulations of the Institution are eligible for their Examinations; they are also eligible for election as Students of the Institution of Mechanical Engineers, Associates of the Society of Engineers, etc.

The usual age for admission to the School is 16 to 17 years, but there is no limit as to the age of Students. They may commence work at the beginning of any term.

Mechanical Engineering (First Year).

The Students spend one Term each in the Drawing Office, the Pattern Shop and Foundry, and the Fitting and Smith's Shop, besides attending Lectures on 'Steam and the Steam Engine,' 'Railways: their Construction and Appliances,' 'Materials and their Manufacture,' and other Special Subjects, including Mathematics.

Civil Engineering (Second Year).

The first Term in this section is devoted to Practical Preparation by actual Levelling, Surveying, Theodolite work, etc., of Plans for a complete Public Work, and the necessary Plans, Estimates, etc., for a Railway.

The second Term is devoted to the Preparation of Working Plans, Calculations, Estimates, etc., of the said Work for the Contractors.

The third Term is utilised for Original Designing, Theory of Structures, and other necessary Calculations, Specifications, etc., for Bridge, Reinforced Concrete and other Work, reporting upon existing Engineering Works, and the testing of Cement.

Debates are held to afford Students an opportunity of gaining confidence in public professional speaking.

At the meetings of the 'Crystal Palace Engineering Society' (affiliated to the Society of Engineers) Students read and discuss papers on Professional subjects. Professional visits to Engineering Works are made from time to time.

Of the Students who have passed through the School, many have obtained appointments as Chief Engineers at home and abroad; and upwards of 1,400 are employed in Engineering work in various countries in the World.

LONDON

ENGINEERING TRAINING

Northampton Polytechnic Institute,

St. John Street, London, E.C.1.

Principal: S. C. LAWS, M.A., M.Sc.

ENGINEERING DAY COLLEGE.

The College provides courses in Civil, Mechanical, Electrical, Aeronautical and Radio Engineering. Each course occupies four years, and includes provision for students to spend two summer periods, April to September, in commercial works. Students should be not less than 16 years of age at entrance.

Fees. **£18** per annum for students residing during term in London, Kent, or (in approved cases) Middlesex and Hertfordshire. **£60** for students resident elsewhere.

EVENING COURSES.

Professional and Trade courses are provided in all branches of Civil, Mechanical, Electrical, Aeronautical, Automobile and Radio Engineering. Special classes in Telegraphy and Telephony are organised for Post Office employees.

Professional courses are recognised for the award of National Certificates in Engineering and are adapted to the requirements of the Associate-Membership examinations of the various engineering institutions. Special courses are provided in preparation for the B.Sc. (Eng.) degree of London University.

Students preparing for University degrees are able to enter as Internal candidates for the University examinations.

Full particulars and prospectuses may be had on application to the Principal.

LONDON

ENGINEERING TRAINING

University of Birmingham.

Chancellor—THE VISCOUNT CECIL OF CHELWOOD.
Pro-Chancellor—SIR GILBERT BARLING, BART., C.B., C.B.E., F.R.C.S.
Vice-Chancellor and Principal—C. GRANT ROBERTSON, M.A., C.V.O., LL.D.
Vice-Principal.—F. W. BURSTALL, M.Sc., M.A.
Secretary—C. G. BURTON, M.Com.

Departments of Civil, Mechanical & Electrical Engineering.

The FULL COURSES EXTEND OVER FOUR YEARS, and students who enter after Matriculation and who pass successfully the Examinations at the end of each year WILL BE ENTITLED to the DEGREE of BACHELOR OF SCIENCE in the branch of Engineering to which they devote themselves.

The Technical Engineering Classes include:—

Lectures on the Strength of Materials, Theory of Steam, Gas, and other Heat Engines, Hydraulics, Machine Design, Strength of Structures, Distribution of Power.

Drawing: Design of Tools, Prime Motors, Dynamos, and other forms of Machinery.

Courses in Civil Engineering, including Constructional Work in Masonry and Steel, Railway Work, Dams, Bridges, and Water Engineering.

Field Work: Practical Surveying in the Field throughout the Summer Term.

Engineering Laboratory: Determination of the Strength of Materials, including Compressive, Bending, Tensile, and Torsion Tests, Experimental Study of the Steam Engine and Boiler, Frictional Efficiency Tests, the Flow of Water over Weirs and through Orifices, etc.

Lectures and Demonstrations on all branches of Electrical Engineering.

Electrical Laboratory: Testing of Continuous and Alternate Current Machinery: Electrical Instruments, Meters, Lamps and Batteries: Insulation and Magnetic Testing Work.

The Courses also include Instruction in Mathematics, Physics, Chemistry, Geology, and Metallurgy.

For detailed Syllabus, with full particulars of **University** Regulations, Lecture and Laboratory Courses, Fees, Scholarships, etc., apply to the Secretary.

BIRMINGHAM

ENGINEERING TRAINING

TECHNICAL COLLEGE BRADFORD

DAY COURSES

FULL-TIME (DAY) COURSES extending over three or four years, and leading to the Diploma of the College, are arranged in the following Departments :

TEXTILE INDUSTRIES
CHEMISTRY
DYEING
MECHANICAL ENGINEERING
CIVIL ENGINEERING, ARCHITECTURE and BUILDING
ELECTRICAL ENGINEERING
BIOLOGY
COMMERCE and BANKING
PHARMACY

These Courses are designed to meet the needs of Students wishing to present themselves for the Degree Examinations of the London University.

Special facilities are available for advanced study and research.

EVENING COURSES

PART-TIME (EVENING) COURSES are also arranged, on the successful completion of which students are awarded Senior and Advanced Course Certificates.

Further particulars and prospectuses may be obtained on application to the PRINCIPAL, Technical College, Bradford.

BRADFORD

ENGINEERING TRAINING

Heriot-Watt College,

EDINBURGH.

Governors—THE GOVERNORS OF THE HERIOT-WATT COLLEGE.

Chairman—THE RIGHT HON. LORD PROVOST SIR ALEXANDER STEVENSON.

Vice-Chairman—ROBERT WILSON, Esq.

Principal—A. P. LAURIE, M.A., D.Sc., F.R.S.E., sometime Fellow of King's College, Cambridge.

DAY TECHNICAL COLLEGE

COURSES OF INSTRUCTION IN

MECHANICAL ENGINEERING, ELECTRICAL ENGINEERING, APPLIED CHEMISTRY, MINING.

The Heriot-Watt College offers complete Courses of Instruction in these subjects, and a Diploma or Certificate at the end of the Course.

The complete Diploma Courses in Mechanical Engineering and Electrical Engineering last over three years, and in Applied and Analytical Chemistry over four years.

The Diploma Course in Mining (Coal, Metalliferous and Oil) lasts over three years.

Arrangements have been made with local Engineering Firms for shortened apprenticeships for students who hold the Diploma of the College.

The Associateship of the College in Chemistry is recognised by the Institute of Chemistry as a qualification exempting students from the examinations for the Associateship of the Institute of Chemistry. In the Chemistry Department there are also Courses in Bio-Chemistry, and in Pharmaceutics for the Professional Examinations of the Pharmaceutical Society of Great Britain.

Special arrangements have been made for **POST-GRADUATE COURSES** in **ELECTRICAL ENGINEERING, PRIME MOVERS,** and **APPLIED CHEMISTRY.** Students wishing to take these post-graduate Courses must either hold the B.Sc. of some University or the Diploma of the Heriot-Watt College or of the Royal Technical College, Glasgow.

There is also a Course extending over two Winter Sessions for Clerks of Works, Builders' Clerks, and Surveyors' Apprentices.

EVENING CLASSES.—Advanced Classes in various Departments of Pure and Applied Science, Commerce, and Languages, which will prove of use to students who have already taken a Degree or who are studying for a Degree, are held in the College in the Evening.

FEES.—Day Classes. Composition Fees for Diploma Courses, £27 to £31 10s. per annum. **Evening Classes,** 10s. to 75s.

All particulars regarding the College Classes, both Day and Evening, can be obtained from the PRINCIPAL at the College.

For the Scheme for Degrees in Civil, Electrical and Mechanical Engineering, Mining and Metallurgy, and Technical Chemistry arranged with the University of Edinburgh, see University Calendar, or the Calendar of Heriot-Watt College.

EDINBURGH

ENGINEERING TRAINING

The Royal Technical College, GLASGOW.

The College is affiliated to the University of Glasgow, and the Degrees of the University in Engineering, Applied Chemistry, Architecture, and Pharmacy are open to students.

The Diploma of the College is granted in the following Departments:—

CIVIL ENGINEERING.
Professor GEORGE MONCUR, B.Sc., M.Inst.C.E.

MECHANICAL ENGINEERING.

CHEMICAL ENGINEERING.
Professor A. L. MELLANBY, D.Sc., M.I.Mech.E.
Associate Professor WM. KERR, Ph.D., A,R.T.C., M.I.Mech.E.

ELECTRICAL ENGINEERING.
Professor STANLEY PARKER SMITH, D.Sc., M.I.E.E.

MINING ENGINEERING.
Professor DANIEL BURNS, M.Inst.M.E.

NAVAL ARCHITECTURE.
Lecturer, Mr. WM. M. GRAY, B.Sc., M.I.N.A.

CHEMISTRY.
Director of the School of Chemistry, and 'Young' Professor of Technical Chemistry—THOMAS GRAY, D.Sc., LL.D., Ph.D., F.I.C.
Professor of Organic Chemistry—FORSYTH J. WILSON, D.Sc., Ph.D., F.I.C.
Professor of Inorganic and Analytical Chemistry—ROBERT M. CAVEN, D.Sc., F.I.C.

METALLURGY.
Professor JOHN H. ANDREW, D.Sc.

BUILDING.
Superintendent—Prof. T. H. HUGHES, F.R.I.B.A., A.R.C.A.

TEXTILE MANUFACTURE.
Lecturer, Mr. WM. WATSON.

DYEING.
Lecturer, Mr. ALEC B. STEVEN, B.Sc., F.I.C.

SUGAR MANUFACTURE.
Lecturer, Mr. T. H. P. HERIOT, F.I.C., F.C.S.

A Course for a Joint Diploma in ARCHITECTURE has been arranged in conjunction with the Glasgow School of Art.

The Diploma Courses extend over either three or four sessions, and the fee per session is Twenty-five Guineas.

Full Courses of Instruction are also provided in the Schools of Navigation, Pharmacy and Bakery.

Prospectuses (free) will be sent on application to the Director.

GLASGOW

ENGINEERING TRAINING

THE

University of Leeds.

Three or Four Year Courses in

Leeds.

LEEDS

ENGINEERING TRAINING

The University of Liverpool

FACULTY OF ENGINEERING.

DEAN: Professor C. O. BANNISTER, M.ENG., ASSOC. R.S.M., F.I.C., M.INST.M.M.

THE University awards the degrees of B.Eng., M.Eng., D.Eng., Ph.D., and a Certificate and Diploma in Engineering.

Degree candidates must pass an approved Matriculation Examination. Candidates for a Certificate (which leads to a Diploma) must have: (i) Been engaged in Practical Engineering. (ii) Followed approved courses in a Technical School.

The courses are designed for students desiring to qualify as MECHANICAL, ELECTRICAL, CIVIL or MARINE ENGINEERS, as NAVAL ARCHITECTS and METALLURGISTS or METALLURGICAL ENGINEERS. These courses cover the subjects of Examination for Associate Membership of the Institutions of Civil, Mechanical, and Electrical Engineers. The Institutions named, subject to certain conditions, accept the degree of B.Eng. in lieu of part, and in some cases the whole, of the examinations for Associate Membership. The various departments are housed in commodious and well-equipped buildings, and provide ample facilities for research.

A prospectus of the Faculty, giving particulars of courses and a large number of Entrance and Post-graduate Scholarships, may be had on application to the undersigned,

EDWARD CAREY, *Registrar.*

LIVERPOOL

ENGINEERING TRAINING

THE

Dressing of Minerals

By HENRY LOUIS, M.A., D.Sc., A.R.S.M.

Member of the Institution of Civil Engineers; Fellow of the Institute of Chemistry of Great Britain; Fellow of the Geological Society; Member of the Institution of Mining Engineers; Emeritus Professor of Mining, Armstrong College, Newcastle-on-Tyne.

THE 'Dressing of Minerals' is a term that is intended to include all the series of operations that intervene between the extraction of a mineral from its natural deposit and its production in a condition ready for sale or for further use in the arts or manufactures; it practically covers the whole series of operations which have for their object the separation of a mass of mixed minerals into its mineralogical constituents, or the cleaning of ore constituent from the accompanying mineral or minerals which may be looked upon from the technical point of view as the impurities of the former.

The object of Professor Louis is to give an account of the theory and practice of the subject, and the present volume—the first English treatise on the subject—will prove of the greatest service to the miner or metallurgist who desires to understand the principles upon which the art is based, as also to the manufacturer who supplies the necessary appliances, and above all to the student who is preparing for either of the above professions.

SUMMARY OF CONTENTS.

I.—General Considerations. II.—Volumetric Sizing. III.—Sorting and Washing. IV.—Comminution. V.—Separation by Specific Gravity. VI.—Appliances depending essentially on Vertical Fall. VII.—Jigs. VIII.—Horizontal Current Separators. IX.—Shaking Tables. X.—Pneumatic Separation; Magnetic Separation; Electrostatic Separation; Separation by Surface Tension. XI.—Accessory Appliances. XII.—General Construction of Dressing Works.

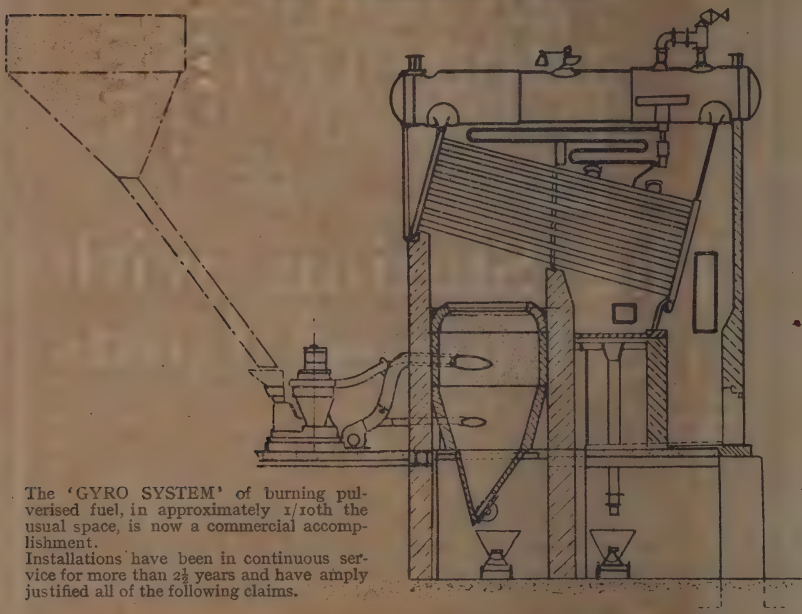
Fuel, Metallurgical and Refractory Technologists

Proprietors of the
- 'GYRO' Patented FURNACES.
- 'GYRO' Patented PULVERISERS.
- 'GYRO' Patented PULVERISED FUEL SYSTEMS.
- 'GYRO' Patented GAS PRODUCER.
- 'LEOLITE' Regd. REFRACTORIES.



The 'GYRO SYSTEM' of burning pulverised fuel, in approximately 1/10th the usual space, is now a commercial accomplishment.
Installations have been in continuous service for more than 2½ years and have amply justified all of the following claims.

The distinctive advantages attained by the Gyro System as applied to Water-tube Boilers are:—

(1) Occupies same space as a Chain Grate.
(2) Controllable location of combustion zone.
(3) Withdrawal of ash in cooled nodulised form, with Carbon less than ·1 %.
(4) Ratio of Capital Cost per lb. of Steam per hour—£1 to 15 lbs.
(5) 10 lbs. to 12 lbs. Coal per hour burned per cubic foot of combustion space.
(6) Power per ton of Coal pulverised and injected from 7 K.W.H. to 10·6 K.W.H., according to size of Pulveriser.
(7) Total Capital Maintenance, and Operating Charges approximately 50 % less than old-fashioned methods.
(8) Efficiency guaranteed according to Boiler from 80 % to 90 %.
(9) Plant erected and operating within six to eight weeks.

Repeat Orders have been secured.

The Station with the Lowest Costs

TO attain this enviable position—to be at the *bottom* for low running costs and at the top for efficiency—is the aim of every ambitious station engineer. The stations with the established reputations are those which have installed 'Bennis' Machine Stokers and coal-handling plant. The truth of our assertion can be easily tested by reference to Garcke's Manual.

OUR catalogue on 'Coal and Ash Plant' is now available. If you are looking for ways and means of economising labour in power houses, you will find it in this book, which is packed with interesting information, figures, and photographs of actual installations. We shall be pleased to send the book on request. Ask for Catalogue YB 724.

UNRIVALLED AS AN ADVERTISING MEDIUM

THE ENGINEER'S YEAR-BOOK FOR 1929

This unique publication is the recognised standard reference book on British Engineering Practice. It is consulted daily by all the most influential engineers throughout the world, including advisers to Governments, Municipalities, Railway, Shipping, and Mining Companies, as well as by Directors, Managers, and Technical Staffs of Engineering Works, Iron and Steel Foundries, Shipyards, Industrial Plants, &c., also by Contractors, Manufacturers, and Power Users generally.

Announcements for the 1929 EDITION (now in preparation) should be sent as soon as possible to the PROPRIETORS, 7 Stationers' Hall Court, E.C.4

'This excellent Annual really requires no commendation. It is among the most useful books of reference of its class which exists, if, indeed, it is not actually the most useful, and it is used by engineers the world over.'
—THE ENGINEER.
